## APPENDIX XVI

# EPI On-site Visit Sampling Methodology and Protocol

---

### Sampling Methodology

For the 2024 EPI impact evaluation, 60 on-site visits were conducted with participants. The selected samples included 60 EPI participants as well as 60 back-up participants that had at least four different products installed from January through July 2024.

The sample was verified to be representative of the population within  $\pm 10\%$  of the proportion of participants served by a delivery agent (DA) and a representative mix of product installations. As described earlier, the criteria for selecting the sample were that at least four different products were installed.

### On-site Visit Protocol

The on-site visits were conducted to verify the number of products installed and recorded in the tracking system. The on-site observation protocol was developed to serve two main purposes: (1) Establish the installation rates of products; and (2) determine whether any products had been removed and, if any, the reasons for their removal. The Evaluator then validated the assumptions used to calculate the unitary savings value for each product category by collecting the following types of information during the visits:

- › The locations of the new lamps (indoors or outdoors)
- › The domestic hot water (DHW) heating source and tank size
- › The number of faucets and showerheads in a home
- › The locations of faucet aerators

The Evaluator also collected information about the space heating source and whether an air conditioner was used. This information was useful in determining the impact of installed lighting measure interactive effects.

## On-site Visit Data Collection Form

Fields in light gray are filled prior to the visit based on the information in the tracking sheet. Other fields are filled during the site visit and base on on-site observations and the contact's statement.

### 1) General Information

|                      |                     |   |    |   |                   |   |    |   |

Notes:

## APPENDIX XVII

### EPI Algorithms for Free-Ridership Calculation

The tables below present the algorithms used to calculate the free-ridership levels for EPI measures. The algorithms are based on participant survey questions designed to assess program influence on variables such as planning, cost, effort, timing, and quantity on participant decision-making. To better evaluate free-ridership based on which measures were added to participants' homes, three separate algorithms were used, one for LED lamps, one for smart thermostats, and one for all DHW measures. The previous versions of the algorithms are presented on the left as comparisons.

#### EPI – Free-Ridership Algorithm for LED Lamps

Table 1: Free-Ridership – LEDs

| Previous Algorithm |                                                                                                                                                                                     |                           |                     | 2024 Algorithm                                                                                                                                                                                                      |                                              |                     |

## APPENDIX XVIII

### EPI Algorithm for Participant Spillover Calculation

Participant spillover was measured using a participant survey. Participants were asked, pursuant to participating in EPI, whether they implemented any additional energy efficiency measures without benefitting from any rebates offered by E1 program components. If participants did have additional measures implemented, they were asked the type of measure and quantity installed. Subsequently, another question was asked to quantify the level of influence the program component had on the participant's decision to implement the additional measures. The value established regarding this level of influence was used to determine the portion of additional savings attributable to the program component.

Then, the level of participant spillover was established by dividing the total amount of additional savings attributable to the program component by the total amount of savings achieved through program component participation by all survey respondents.

Table 1 illustrates the methodology used to calculate the participant spillover level.

**Table 1: Spillover (for Electrical Savings)**

## APPENDIX XIX

### EPI Jurisdictional Scan Findings

Econoler performed a scan across various jurisdictions throughout Canada and the United States (US) to identify other measures that could be installed by electricians under EPI. This appendix presents the scanned jurisdictions and the measures they include. Measures already included in EPI are in **blue**. Measures not suited for EPI are in **light blue**; those includes measures that require a large amount of time to install, products that are too voluminous to keep in stock, and measures that requires piercing or opening walls or ceilings. Measures that might be added to the EPI offering are in **bold**.

**Table 1: Jurisdictional Scan Findings**

| Jurisdiction                            | Program                                       | Entity Offering the Program | Energy Efficiency Measures                                                                                                                                                                                                                                                                          | Source                                                                                                                                                                                                                                                                  |

# APPENDIX XX

## EPI 2024 Recommendations

This appendix summarizes all the recommendations made by the Evaluator as part of the 2024 EPI evaluation.

| Section           | Recommendations                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Executive Summary | Recommendation #1: To improve the smart thermostat installation rate, explore and implement strategies to reduce the number of participants disconnecting this product due to dissatisfaction. For example, follow-up calls could be conducted, installers could educate more participants on this product, or additional educational material on this product could be shared with participants. |

## APPENDIX XXI

### Green Heat Past Participant Survey Questionnaire

#### HOME ENERGY ASSESSMENT/GREEN HEAT PAST PARTICIPANT SURVEY

**Table 1: Overview of Data Collection Activity**

## Introduction

We at Narrative Research are performing an evaluation of energy efficiency services provided by Efficiency Nova Scotia. Our records indicate that you or your household recently participated in the **<INSERT PROGRAM NAME>** program.

We would appreciate your help in answering a very short survey about this program, it will take perhaps 2 or 3 minutes.

**[IF GH]:** As a reminder, the program provides a rebate for the installation of home heating equipment such as **<INSERT MEASURE >**.

**[IF HEA]:** As a reminder, this program involves having an energy advisor conduct an assessment of your home, including a blower door test, and provide participants with energy efficiency upgrade recommendations. The federal Canada Greener Homes Grant initiative is delivered with Efficiency Nova Scotia through the Home Energy Assessment (HEA) program, so you may instead recall participating in the Greener Homes program.].

### A. Verification and Recall

A1. We understand you participated in the **<INSERT PROGRAM>** program in **<PARTICIPATION YEAR>** for your house located at **<ADDRESS>** **[IF GH, ADD]** by installing a **<INSERT MEASURE>**. Is that correct?

1. Yes **[CONTINUE]**
2. No **[END]**

### B. Verification of Actions Taken

The following questions concern **<IF PROGRAM=HEA>** “the energy efficiency upgrades” **<IF PROGRAM=GH>** “the **<INSERT MEASURE >** installation project” **<FOR ALL>** that you completed through your participation in **<INSERT PROGRAM>** in **<PARTICIPATION YEAR>** for the house located at **<ADDRESS>**

B1. **<IF PROGRAM=HEA>** “Were your energy efficiency upgrades” **<IF PROGRAM=GH>** “Was your **<INSERT MEASURE>**”, **<FOR ALL>** installed as part of a renovation project that involved adding floor area to your home? By adding floor area, we mean that you added an extension to your home, such as a new floor or a new room that was not there before your renovation project.  
**PROGRAM B1 AND B2 AS MANDATORY, ALL OTHER QUESTIONS (EXCEPT A1) WILL BE PROGRAMMED AS OPTIONAL**

1. Yes
2. No

- B2. **<IF PROGRAM=HEA>**, “Were your energy efficiency upgrades” **<IF PROGRAM=GH>** “Was your **<INSERT MEASURE>**” **<FOR ALL>** installed as part of a renovation project that involved heating rooms that were previously not heated or were only minimally heated (for example,. at a temperature lower than 15°C)? Examples of such renovation projects would be that, you finished your basement and started heating it, or you could have changed a sunroom so that it became heated throughout the year whereas it previously was not.
1. Yes, ***the renovation project involved*** heating rooms that were previously not heated/were minimally heated
  2. No ***the renovation project did not involve*** heating rooms that were previously not heated/were minimally heated
- B3. **<IF PROGRAM=HEA OR MEASURE=HEAT PUMP>**Did you have a fireplace or wood stove in your home **<IF PROGRAM=HEA>** “before having your home evaluated by an energy advisor” **<IF PROGRAM=GH>** “before installing your heat pump”? **ACCEPT MULTIPLE ‘YES’ RESPONSE**
1. Yes, a fireplace
  2. Yes, a wood stove
  3. No
- B4. **[IF B3= 1 AND/OR 2]** How, if at all, did usage of your [a. ‘fireplace’ / b. ‘wood stove’] change after you installed your energy efficiency upgrades? Did your usage ...: **[READ – POSE SEPARATELY FOR ‘A’ AND ‘B’, IF 1 AND 2 SELECTED IN B3]**
1. Increase a lot
  2. Increase a little
  3. Stay the same
  4. Decrease a little
  5. Decrease a lot
  6. Did not notice a change
- B5. **[ASK IF PROGRAM=HEA]** Through the **<INSERT PROGRAM>**, have you installed any type of heat pump, including mini-split, central or geothermal?
1. Yes
  2. No
- B6. **[ASK IF B5=1 OR PROGRAM=GH AND MEASURE=HEAT PUMP]** Prior to installing your heat pump, did you already have a working air conditioner in your home? **[DO NOT READ RESPONSES]**
1. Yes
  2. No

**END:** Thank you for completing today’s survey – your help is greatly appreciated.

## APPENDIX XXII

### Green Heat Past Participant Survey Results

**TABLE B1:** Was your Green Heat installed as part of a renovation project that involved adding floor area to your home? By adding floor area, we mean that you added an extension to your home, such as a new floor or a new room that was not there before your renovation project.

| OVERALL %       |     |
|-----------------|-----|
| SAMPLE SIZE (#) | 240 |
| Yes             | 4%  |
| No              | 96% |

**TABLE B2:** Was your Green Heat installed as part of a renovation project that involved heating rooms that were previously not heated or were only minimally heated (for example, at a temperature lower than 15°C)?

Examples of such renovation projects would be that, you finished your basement and started heating it, or you could have changed a sunroom so that it became heated throughout the year whereas it previously was not.

| OVERALL %                                                                                                      |     |
|----------------------------------------------------------------------------------------------------------------|-----|
| SAMPLE SIZE (#)                                                                                                | 240 |
| Yes, the renovation project involved heating rooms that were previously not heated/were minimally heated       | 16% |
| No, the renovation project did not involve heating rooms that were previously not heated/were minimally heated | 84% |

**TABLE B3:** [MEASURE=HEAT PUMP] Did you have a fireplace or wood stove in your home before installing your heat pump?

| OVERALL %         |     |
|-------------------|-----|
| SAMPLE SIZE (#)   | 204 |
| Yes, a fireplace  | 15% |
| Yes, a wood stove | 31% |
| No                | 55% |

**TABLE B4a:** [IF B3=1] How, if at all, did usage of your fireplace change after you installed your energy efficiency upgrades? Did your usage ...:

| OVERALL %               |     |
|-------------------------|-----|
| SAMPLE SIZE (#)         | 30  |
| Increase a lot          | 7%  |
| Increase a little       | 7%  |
| Stay the same           | 30% |
| Decrease a little       | 17% |
| Decrease a lot          | 30% |
| Did not notice a change | 10% |

**TABLE B4b:** [IF B3=2] How, if at all, did usage of your wood stove change after you installed your energy efficiency upgrades? Did your usage ...:

| OVERALL %               |     |
|-------------------------|-----|
| SAMPLE SIZE (#)         | 64  |
| Increase a lot          | 2%  |
| Increase a little       | 6%  |
| Stay the same           | 30% |
| Decrease a little       | 23% |
| Decrease a lot          | 31% |
| Did not notice a change | 8%  |

**TABLE B6:** [MEASURE=HEAT PUMP] Prior to installing your heat pump, did you already have a working air conditioner in your home?

| OVERALL %       |     |
|-----------------|-----|
| SAMPLE SIZE (#) | 204 |
| Yes             | 30% |
| No              | 70% |

## APPENDIX XXIII

### Green Heat Tracking Sheet Audit

This appendix presents the main results of the tracking sheet audit performed by the Evaluator, which was aimed at:

- › Verifying that all data fields required for the evaluation were included and filled out in the tracking sheet submitted by E1
- › Ensuring that tracked results were accurate by:
  - › Verifying that parameters used to calculate program results (gross and net electrical energy and peak demand savings at the generator) were consistent with previous evaluation results
  - › Validating that all calculation steps were performed consistently

Table 1 presents the corrected tracked savings resulting from all changes made by the Evaluator.

**Table 1: 2024 Green Heat Corrected Tracked Savings**

| Program Component Results                  | Value Tracked by E1 |      | Corrected Tracked Value |      | Relative Difference |
|--------------------------------------------|---------------------|------|-------------------------|------|---------------------|
|                                            | Value               | Unit | Value                   | Unit | Value               |
| <b>Green Heat</b>                          |                     |      |                         |      |                     |
| Gross Energy Savings at the Generator      | 4.519               | GWh  | 4.711                   | GWh  | 4.26%               |
| Gross Peak Demand Savings at the Generator | 3.907               | MW   | 3.915                   | MW   | 0.21%               |
| Net Energy Savings at the Generator        | 2.377               | GWh  | 2.478                   | GWh  | 4.27%               |
| Net Peak Demand Savings at the Generator   | 2.142               | MW   | 2.143                   | MW   | 0.05%               |

As shown in Table 1, differences between the tracked and corrected values are found in the gross and net electrical energy savings as well as the gross and net peak demand savings results. Those differences are mainly caused by corrections made by the Evaluator.

For electrical energy savings:

- › The definition of fully and mainly electrically heated used to allocate savings for mini-split heat pump (MSHP) measures was not consistent with that used in the billing analysis, because fireplaces were considered as a secondary non-electrical heating system that put participants in the mainly electrical category, when they should have been considered fully electrically heated. This explains the most of the difference between the tracked and corrected tracked values.
- › The adjustment of the baseline for some wood fireplace inserts and wood and pellet stoves from a heat pump baseline to an electric resistance baseline according to their primary and secondary heating systems
- › The adjustment for discrepancies between unitary savings and reported electrical energy savings for some wood fireplace inserts and wood and pellet stoves
- › The adjustment from fully electrically heated to mainly electrically heated for some mini-split heat pump measures because a secondary heating system was installed

- 
- › The adjustment of the nominal heating capacity as well as the heating capacity and COP at -15°C used for mini-split heat pumps for some projects, based on values found in the NEEP Cold Climate Air Source Heat Pump Product list

For peak demand savings:

- › The adjustment to the nominal heating capacity used for some mini-split heat pumps, based on values found in the NEEP Cold Climate Air Source Heat Pump Product list.
- › The correction of NTGRs for all three-element water heater and domestic hot water timer measures.

## APPENDIX XXIV

# Green Heat Detailed Methodology and Billing Analysis

### Background

After inconclusive results in 2023, a billing analysis was again conducted for Green Heat as part of the 2024 DSM evaluation to obtain measured electrical energy savings generated through the installation of mini-split heat pumps (MSHPs) and wood or pellet stoves or fireplace inserts. MSHPs are the most significant measures in Green Heat, followed by wood or pellet stoves or fireplace inserts. The 2024 billing analysis served to update the results of the 2017 billing analysis for MSHPs, while it was conducted for the first time for wood or pellet stoves or fireplace inserts since these measure savings were previously estimated using energy modelling as part of the 2013 evaluation. Unlike the billing analysis conducted in 2023, **AMI data**, which started to be progressively available for residential customers in 2020, were used for the 2024 billing analysis to improve the quality of the analysis.

### Methodology

The billing analysis consisted of calculating the change in electrical energy consumption by comparing levels before and after participation in Green Heat for a group of recent participants (treatment group). To account for variations in electrical energy consumption due to factors other than Green Heat participation, the Evaluator selected a control group of Green Heat participants from previous years and deducted the change in electrical energy consumption observed for that group over the same period (difference-in-differences approach). Subtracting the change in control group electrical energy consumption (i.e. a change that is not linked to the program component) from that of the treatment group ensures that **only savings attributable to Green Heat are captured** and avoids capturing other effects that can have an impact on energy consumption (e.g. the COVID-19 pandemic) because both the treatment and control groups are impacted by such effects.

Electrical energy savings are obtained from the AMI data and weather-normalized so they can be compiled and compared. For MSHPs, normalized electrical energy savings are divided by the nominal capacity of installed units to obtain unitary savings as a function of capacity. For wood/pellet stoves/fireplace inserts, unitary savings are presented on a per-unit basis.

The following subsections detail how AMI data were used to calculate electrical energy savings and ultimately unitary savings.

### Selection of the Treatment and Control Groups

The initial treatment group included 1,211 Green Heat participants (1,014 for MSHP measures and 197 for wood/pellet stoves/fireplace inserts) who were selected based on the following criteria:

- › Be mainly electrically heated before Green Heat participation, meaning that the primary heating fuel identified in the tracking sheet was electrical. In addition, for participants who installed a MSHP, have a primary heating system other than a heat pump or thermal storage system before Green Heat participation
- › Have an installation date no later than October 2023 to ensure a full year of post data
- › Have an installation date no earlier than October 2022 to avoid overlap with control group participation

Among the 1,211 participants selected based on these criteria, AMI data were available for 1,101 participants.

The initial control group included a total of 2,810 participants who were selected based on the following criteria:

- › Be mainly electrically heated before Green Heat participation
- › Have an installation date no later than October 2021
- › Have an installation date no earlier than January 2020

Among the 2,810 control group participants selected based on these criteria, AMI data were available for 2,305 participants.<sup>2</sup>

By selecting the control group among a sample of past Green Heat participants, the Evaluator ensured that control group participants had similar characteristics to treatment group participants, as recommended for matched control group approaches in Chapter 8 of the Uniform Methods Project (UMP). The process to match control and treatment participants is further described below.

### AMI Data Preparation

AMI data for treatment group and control group participants were obtained from two sources:

- › Nova Scotia Power (NS Power) for the period between the moment AMI data became available (2020) and November 2023
- › EfficiencyOne for the year 2024 (in May 2023, EfficiencyOne started to have access to AMI data in the NS Power system)

In both cases, AMI data were aggregated on a monthly basis (i.e. only monthly kWh consumption values were available).

Before performing the billing analysis, the Evaluator validated the annual consumption load shapes for each treatment and control group participant to exclude those participants with inconsistent consumption data. Data that matched the following criteria were excluded:

- › Nil consumption or missing data in the study period
- › Very high or very low peaks in the study period
- › Numerous abnormal variations in the consumption pattern (extremely high consumption months followed by close to zero consumption months for instance)

As a result of the above criteria, about 5% of the sample was excluded. The control group remained largely sufficient to have a control match for each treatment group participant.

### Control-Treatment Participant Matching

To determine the best suited control group participant for each treatment group participant, the Evaluator first applied a set of minimum conditions with which to comply:

- › The installation date of the control participant must be at least one year before the installation date of the treatment participant.
- › The weather station must be the same.
- › The measure installed (MSHP or wood/pellet stoves/fireplace insert) must be the same.

---

<sup>2</sup> As it was the case for the treatment group, the Evaluator kept only participants with a high level of confidence in the NS Power data matching in the analysis.

These conditions left treatment participants with more than one potential control participant. The point system presented in Table 1 below was then used to provide a score for each potential control participant. The control participant with the highest score was then considered the ideal match and was assigned to the given treatment participant.

**Table 1: Details on the Point System Used for the Selection of Control Participants**

| Parameters                                                                                  | Points                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Average daily consumption of treatment and control candidates after their installation date | <p>Add a maximum of 2 points based on a function of the relative difference between the average daily consumption of treatment and control candidates using a sigmoid function that yields approximately the following points:</p> <ul style="list-style-type: none"> <li>› 2 points if difference is 10%</li> <li>› 1 point if difference is 25%</li> <li>› 0 points if difference is 50% or more</li> </ul> |

It should be noted that each participant had different pre and post-program periods based on when participation in Green Heat occurred. Given this, each treatment group participant was assigned one control group participant, and the dates of the pre and post-periods of each treatment participant were applied to their matched control participant for the next steps of the billing analysis.

### Weather Normalization

The Evaluator normalized the consumption values obtained from AMI data using normal weather data to obtain annual consumption values that are aligned with a typical meteorological year. A regression was used to determine how consumption related to heating and cooling degree days was associated with the weather station and billing dates of each control and treatment participant. Multiple iterations were made to select the most appropriate balance temperature to calculate the heating and cooling degree days of each control and treatment participant.

Then, the normal heating and cooling degree days were included in each regression to obtain energy consumption during a typical weather year. The Evaluator calculated the normal heating and cooling degree days based on the previous 15 years (2008-2023) for the five weather stations selected for the analysis (Debert, Greenwood, Halifax, Sydney, and Yarmouth).

## Energy Savings Calculation

Figure 1 below illustrates how electrical energy savings were obtained by calculating the difference in the treatment group normalized annual consumption of each participant for the year before and after program participation and deducting the difference observed in the control group normalized annual consumption for the same period as the treatment participant to which the control participant was assigned (difference-in-differences approach).

**Figure 1: Electrical Energy Savings Calculation Using AMI Data**

- › T\_Pre: Normalized annual consumption of the treatment participant for the year before the installation
- › T\_Post: Normalized annual consumption of the treatment participant for the year after the installation
- › C\_Pre: Normalized annual consumption of the assigned control participant for the year before the installation of the assigned treatment participant
- › C\_Post: Normalized annual consumption of the assigned control participant for the year after the installation of the assigned treatment participant

Then, for MSHPs, total energy savings were divided by total installed MSHP capacity to obtain a unitary savings value as a function of MSHP capacity.

For wood/pellet stoves/fireplace inserts, total energy savings were divided by the total number of installed units to obtain a unitary savings value on a per-unit basis.

## Use of Past Participant Survey Results

Given the inconclusive results of 2023 billing analysis, it was hypothesized that some participants included in the billing analysis may have added heated floor area to their home around the same time as their participation in Green Heat (e.g. by building a new heated room or extension or by starting to heat a room or area that was previously not heated, such as a newly finished basement). Such participants would have influenced the results of the billing analysis because they would have increased their consumption following participation (i.e. the additional consumption from added heated floor area would have offset the savings from the Green Heat installation and may even exceed them), which would have lowered overall savings results.

To test this hypothesis, past participants were surveyed to identify and exclude from the analysis those who added heated floor area. Due to limited survey results, this was only possible for part of the treatment group, as described below.

## Detailed Results

### MSHP Measures

Table 2 presents the results of the billing analysis for the Green Heat MSHP measure. Treatment participants who mentioned adding heated floor area as part of their Green Heat renovation project were excluded from the analysis. In Table 2, results of the previous billing analysis (conducted as part of the 2017 evaluation) are presented in between brackets to provide a comparison point.

**Table 2: MSHP Billing Analysis Results**

| Scenario          | Number of Treatment Participants | Average Heating Capacity (Btu/h) | Average Variation in Energy Consumption of Treatment (Tpre-Tpost, kWh) | Average Variation in Energy Consumption of Control* (Cpre-Cpost, kWh) | Average Energy Savings (kWh) | Savings (kWh/Btu/h) | Margin of Error** (kWh/Btu/h) |
|-------------------|----------------------------------|----------------------------------|------------------------------------------------------------------------|-----------------------------------------------------------------------|------------------------------|---------------------|-------------------------------|
| Fully Electrical  | 99                               | 17,702                           | 2,197                                                                  | 684                                                                   | 1,514<br>[3,336]             | 0.0855<br>[0.179]   | 0.054                         |
| Mainly Electrical | 24                               | 17,509                           | 376                                                                    | 591                                                                   | -215<br>[1,328]              | -0.00123<br>[0.060] | 0.094                         |
| Overall           | 123                              | 17,664                           | 1,842                                                                  | 665                                                                   | 1,177                        | 0.0666              | 0.047                         |

\*The control group participants selected specifically for the treatment participants who did not add heated floor area exhibited some unexpected variations between the fully electrical and mainly electrical groups, which could be due to small sample sizes. The Evaluator therefore chose to use the average variation in energy consumption for all control participants to calculate unitary savings.

\*\*Margins of errors presented in this table are estimates calculated on the ratio of Tpre-Tpost and the modelled savings. The impact of the Cpre-Cpost deduction was not considered in the calculation.

The 2024 average electrical energy savings by capacity decreased significantly compared to the previous evaluation. The addition of control groups and other small changes to the methodology are partially responsible for that, although, even when comparing the variation in energy consumption for the treatment group only, the decrease is notable. Mainly electrical households do not generate any savings; the electrical energy savings are negative but are not statistically significant. Since the billing analysis was based only on electricity consumption, it was not possible to measure non-electrical savings, which does not mean that MSHPs do not generate non-electrical savings. In fact, the Evaluator considers that the most likely reason for seeing no electrical energy savings is that the increase in electricity consumption due to transferring a portion of heating consumption from wood or oil to an electric heat pump cancels out the electricity savings achieved by replacing some electric resistance heating by the heat pump. Therefore, the Evaluator recommends using the new value of 0.0855 kWh/Btu/h for fully electrical households and nil savings for mainly electrical households.

The Evaluator compared the savings measured for Green Heat to those measured for HEA participants who only installed heat pumps. On average, HEA participants who only installed heat pumps saved 2,459 kWh, while Green Heat participants generated 1,177 kWh (the overall value is used for comparison since HEA participants include a mix of fully and mainly electrically heated households). These numbers are not directly comparable because the systems installed in HEA and Green Heat differ. When looking at the savings per capacity installed, they are much closer (0.0760 kWh/Btu/h for HEA versus 0.0666 kWh/Btu/h for Green Heat). Indeed, the average capacity of HEA heat pumps is of 32 kBtu/h for participants who only installed a MSHPs compared to just over 17 kBtu/h for Green Heat.

### Wood or Pellet Stoves or Fireplace Inserts Measures

Wood or pellet stoves or fireplace inserts were analyzed as a single measure. As a starting point, the Evaluator separated the results according to the baseline heating system: ASHP or electric resistance baseline.

The Evaluator refined the analysis by removing all participants who indicated using a wood/pellet stoves/fireplace inserts as a secondary heating system prior to the installation of their new equipment. EfficiencyOne indicated that sometimes participants incorrectly wrote this information in their application form because they were thinking about their new heating systems rather than their pre-existing one and that sometimes participants really did have an existing wood/pellet stove/fireplace insert that either was not safe or could meet air quality standards. To ensure that no participant that was already used a wood/pellet stove/fireplace insert was included in the analysis, the Evaluator excluded all participants that indicated that they had previously used such equipment as a secondary heating system. Doing so increased the savings for the electric resistance baseline, but not for the ASHP baseline possibly because of the small sample size of participants with an ASHP baseline. The Evaluator also attempted to exclude participants who had indicated, as part of the past participant survey, that they had added floor area or heating to existing rooms. However, these participants did not have lower savings than surveyed participants that did not add floor area or heating to existing rooms, and removing them would have excessively reduced the sample size from 71 to 16 participants. Therefore, all treatment group participants who installed wood/pellet stoves/fireplace inserts were included in the analysis.

The Evaluator identified one more variable that has a large impact on the measured savings. When fireplace inserts are excluded from other biomass equipment, the variation in energy consumption in the treatment group increases from 1,647 kWh to 1,926 kWh. Indeed, the 14 wood fireplace inserts included in the analysis only demonstrate average energy savings of 232 kWh. When excluding the fireplace inserts from the analysis, the Evaluator obtains the results presented in Table 3. These results no longer differentiate between the electric resistance and ASHP baselines due to small sample sizes.

**Table 3: Wood and Pellet Stove Billing Analysis Results After Removing Fireplace Inserts**

| Scenario      | Number of Treatment Participants | Average Variation in Energy Consumption of Treatment (Tpre-Tpost, kWh) | Average Variation in Energy Consumption of Control (Cpre-Cpost, kWh) | Average Energy Savings (kWh) | Margin of Error (kWh) |
|---------------|----------------------------------|------------------------------------------------------------------------|----------------------------------------------------------------------|------------------------------|-----------------------|
| All Baselines | 71                               | 1,926                                                                  | 465                                                                  | 1,461                        | 1,262                 |

The average electrical energy savings presented in Table 3 are statistically significant since the confidence interval does not include a nil value. The Evaluator believes that this is the most reliable estimate of savings for wood and pellet stoves and should be used to obtain evaluated savings. For fireplace inserts, even though savings are not statistically significant, the Evaluator used 232 kWh for the 2024 evaluation. For future years, the Evaluator recommends considering the removal of fireplace inserts from Green Heat offerings due to their very limited savings.

## Literature review

To put the results of the billing analysis into perspective, the Evaluator conducted a literature review of recent billing analyses and metering studies performed in other jurisdictions for similar energy conservation measures. The Evaluator did not identify any relevant billing analyses or metering studies targeting wood-burning appliances. Regarding MSHPs, one billing analysis and two metering studies were retained and reviewed as they used methodologies and/or results that were relatively comparable to the Evaluator's.

## 2024 Oregon Billing Analysis

This billing analysis<sup>3</sup> conducted in 2024 covered MSHPs installed in Oregon and incentivized by Energy Trust from 2020 to 2022. Energy Trust used an in-house billing analysis tool named the Residential Billing Analysis (REBA) tool. The similarities between Econoler and Energy Trust's methodologies are summarized as follows:

- › Both billing analyses use site-level regression models for weather normalization of each site for pre and post-installation periods.
- › Both use a difference-in-differences approach to evaluate savings whereby the savings attributable to MSHPs correspond to the difference in the average change in annual electricity usage between the treatment and control groups ( $T_{pre} - T_{post} - (C_{pre} - C_{post})$ ).
- › To match the treatment and control groups, both studies use control homes that are in the same geographic area as the treatment homes and that have similar electricity consumption levels.

Energy Trust performed several analyses for sub-samples of their treatment group. One was the presence or not of supplemental heating equipment, which is similar to the Evaluator's fully electric and mainly electric scenarios. The results from both studies for these sub-samples and for the total populations are presented in Table 4 below.

<sup>3</sup> Energy Trust of Oregon, Billing Analysis of Residential Ductless Heat Pump Installations, 2024. Available at: <https://www.energytrust.org/wp-content/uploads/2024/08/FINAL-REBA-DHP-Report-Memo-with-Output-Summaries.pdf>

**Table 4: Econoler and Energy Trust savings results**

| Scenario                           | Number of Participants | Average Savings (kWh) | Sample Description          | Sample N      | Average Evaluated Savings (kWh) |
|------------------------------------|------------------------|-----------------------|-----------------------------|---------------|---------------------------------|
| <b>Econoler Green Heat Results</b> |                        |                       | <b>Energy Trust Results</b> |               |                                 |
| Fully electric                     | 99                     | 1,514                 | W/o supp. Heat              | 628           | 1,494                           |
| Part. electric                     | 24                     | -215                  | W supp. heat                | 159           | 320                             |
| <b>Overall</b>                     | <b>123</b>             | <b>1,177</b>          | <b>Overall</b>              | <b>2,054*</b> | <b>1,032</b>                    |

\*Overall sample size exceeds sum of sub-samples because supplemental heating information was only available for 2022 participants, whereas overall results include participants from 2020-2022.

While the overall savings in both billing analyses are very similar, it should be noted that Oregon has a considerably milder climate than Nova Scotia. For example, the cities of Portland and Halifax have standard heating degree days (base 18°C) of around 2,300 and 4,000 respectively. Monthly average temperatures are between 5°C to 9°C for the months of November to March in Portland compared to -2°C to 6°C for Halifax for the same period. The milder climate has opposing effects:

- › On one hand, winter is shorter and heating loads are lower in Oregon, which may reduce savings.
- › On the other hand, the milder temperatures are favourable for heat pump operation, which can operate at a higher COP for more heating hours.

Assuming all else being equal, it is difficult to estimate which of these effects is more important and whether the expected savings should be higher or lower in Oregon than Nova Scotia.

## 2024 Massachusetts and Connecticut Metering Study

This metering study<sup>4</sup> was conducted in 2024 and covers central heat pumps (CHPs), MSHPs, and ground source heat pumps (GSHPs) installed in Massachusetts and Connecticut between 2021 and 2022. In line with the program offering in those jurisdictions (Mass Save and Energize CT respectively), the study categorizes the results into two installation types:

- › Full displacement (FD) installations whereby the heat pump must be sized to be able to replace the entirety of the existing heating system load hours (whether it is an electric resistance or fossil-fuel appliance). The existing system is still allowed to remain installed as an emergency backup heat source.
- › Partial displacement (PD) installations whereby the heat pump can be sized to meet only part of the heating load.

Guidehouse used on-site heat pump usage and performance data collection at a total of 185 customer homes. Since the performance and consumption of heat pumps are measured in situ, there is no analysis of billing data and no use of a control group.

Green Heat has no requirement regarding the sizing of the heat pump in relation to the building load or the existing heating system. Considering the average installed capacity is around 17 kBtu/h, Econoler considers that most heat pumps installed as part of Green Heat can be considered PD installations (i.e. the existing heating system or a supplemental heating system will still be required to meet part of the heating load hours). Since the Guidehouse savings results are presented in kWh/tonne of installed capacity, Econoler converted Green Heat savings into the same unit. The results are presented in Table 5.

<sup>4</sup> Guidehouse, Massachusetts & Connecticut Heat Pump Metering Study, 2024.

**Table 5: Econoler and Guidehouse Savings Results**

| Scenario                                                                                                                                                                          | Number of Participants | Average Savings (kWh/tonne) | Displacement Type         | Sample         | Electrical Savings (kWh/tonne) |

| Fully electric                                                                                                                                                                    | 99                     | 1,026                       | n/a                       | -              | -                              |
| Part. electric                                                                                                                                                                    | 24                     | -15                         | n/a                       | -              | -                              |
| <b>Overall</b>                                                                                                                                                                    | <b>123</b>             | <b>799</b>                  | <b>PD</b>                 | <b>&lt;33*</b> | <b>1,075</b>                   |
| *The exact sample size for PD MSHP with electric resistance baseline is unknown, although the sample size for the complete PD MSHP sample (including other fuel baselines) is 33. |                        |                             |                           |                |                                |

The cities of Boston and Halifax have standard heating degree days (base 18°C) of around 3,100 and 4,000 respectively. Monthly average temperatures are between -1°C to 7°C for the months of November to March for Boston compared to -2°C to 6°C for Halifax for the same period.

### 2017 Vermont Metering Study

This metering study<sup>5</sup> was conducted in 2017 and covers cold climate ductless mini-split heat pumps (ccHP) installed in Vermont. The study measured in situ performance and consumption of 77 ccHPs for 65 service accounts beginning in November 2015 and through the 2017 heating season.

Cadmus used on-site ccHP usage and performance data collection; therefore, there is no use of a control group. The baseline heating systems of metered homes were mainly non-electrical systems (propane, fuel oil, or wood-burning heating equipment), with a small share of electric resistance heating. However, Cadmus did not meter the consumption of those systems during the pre-installation period. Instead, they calculated heating savings by assuming the capacity provided by the ccHP would directly offset an equivalent amount of heating capacity otherwise provided by the alternate heating system. This approach resulted in the savings per fuel type presented in Figure 2 below.

**Figure 2: Retrofit Savings per Cold Climate Heat Pump Installed (Cadmus, 2017)**

| Percent of MMBtu Provided by Existing Heating System | Heating System Efficiency Assumptions | Fuel Heat Content Assumptions | Savings | Units                                     |
|------------------------------------------------------|---------------------------------------|-------------------------------|---------|-------------------------------------------|
| 7%                                                   | COP of electric resistance heat = 1   | 3.412 kBtu per kWh            | -1,664  | kWh (Includes Electric Resistance Offset) |
| 25%                                                  | 85%                                   | 91.2 kBtu/gal                 | 69.1    | Gallons of Propane                        |
| 46%                                                  | 78%                                   | 138.8 kBtu/gal                | 91.0    | Gallons of #2 Fuel Oil                    |
| 22%                                                  | 60%                                   | 15.3 MMBtu/cord               | 0.66    | Cords Wood                                |

The Evaluator identified some discrepancies or at least some confusion around how to interpret and compile these savings. The Evaluator was able to reach out to one of the authors of the study. Instead of using the savings as presented, the author recommended relying on the ccHP consumption and supplied heating capacity results, which are also provided in the Cadmus report and should be more reliable. Econoler therefore used these figures to estimate savings for an electric resistance baseline.

<sup>5</sup> Cadmus, Evaluation of Cold Climate Heat Pumps in Vermont, 2017.

Since Green Heat is offered to homes fully or mainly electrically heated, Econoler estimated savings from the Cadmus study for an electric resistance baseline. Cadmus' average ccHP results are 2,085 kWh consumed and 21.4 MMBtu of heat energy delivered during the heating season. Since electric resistance has an efficiency of 100%, the baseline consumption would be 21.4 MMBtu. This converts to 6,272 kWh in consumption, resulting in 4,187 kWh in savings for the heating season. Econoler also added 74 kWh in savings for cooling (provided separately in the Cadmus study), resulting in total annual savings of 4,261 kWh. Considering the average heat pump capacity in the Cadmus study is 17,388 Btu/h, Econoler normalized the savings per Btu/h of installed capacity.

**Table 6: Econoler and Cadmus Savings Results**

| Scenario                           | Sample | Average Savings per Capacity (kWh/Btu/h) | Baseline Heating System | Sample | Electrical Savings (kWh/Btu/h) |
|------------------------------------|--------|------------------------------------------|-------------------------|--------|--------------------------------|
| <b>Econoler Green Heat Results</b> |        |                                          | <b>Cadmus Results</b>   |        |                                |
| Fully electric                     | 99     | 0.0855                                   | Electric resistance     | 77*    | 0.245                          |
| Part. electric                     | 24     | -0.00123                                 | N/A                     | -      | -                              |
| Overall                            | 123    | 0.0666                                   | <b>N/A</b>              | -      | -                              |

\*77 ccHPs were metered, but most of them did not have electric resistance as their baseline heating system. As explained above, the savings were estimated by the Evaluator and not directly measured by Cadmus.

As presented in Table 6, the estimated savings from the Cadmus study are almost triple the savings of the Evaluator. Some factors might explain the higher savings observed in the Cadmus study:

- › The approach is fundamentally different from that used in the Evaluator's billing analysis. Cadmus did not actually measure the pre-installation consumption of the baseline system; it is simply calculated using the ccHP-delivered energy and assumed efficiency of the baseline system. Moreover, the savings are not adjusted by using a control group.
- › The study dates to 2017 and the data are from 2015-2017. At that time, the Evaluator and other jurisdictions found higher savings. While this is counterintuitive considering the efficiency of the appliances themselves is expected to increase as the technology improves over the years, the reduction in savings over time may be explained by behavioural aspects. One aspect that was already highlighted by the Evaluator as a possible explanation is the fact that early heat pump adopters might have been more likely to want to maximize its use, which may have resulted in higher savings. Conversely, early and late majority adopters may not trust the technology as much or may not use it as much (e.g. install a heat pump just for cooling, turn it off because it is too noisy, or favour the supplemental heating system that increases comfort). This was also hypothesized by the Cadmus study author during the discussion with Econoler.

The cities of Burlington and Halifax have standard heating degree days (base 18°C) of around 4,100 and 4,000 respectively. Monthly average temperatures are between -7°C to 4°C for the months of November to March for Burlington compared to -2°C to 6°C for Halifax for the same period.

## Summary of Literature Review Findings

The Evaluator reviewed the aforementioned three studies to compare and put into perspective the savings results of the 2024 Green Heat billing analysis.

- › The 2024 billing analysis conducted in Oregon by Energy Trust was the most comparable to Econoler's work in terms of methodology. It also had very similar overall annual savings results of 1,032 kWh compared to 1,177 kWh for Green Heat.
- › The 2024 metering study conducted in Massachusetts and Connecticut by Guidehouse found savings in the same order of magnitude as Green Heat, albeit slightly higher at 1,075 kWh/tonne of capacity compared to 799 kWh/tonne of capacity for Green Heat.
- › The 2017 metering study conducted in Vermont by Cadmus found savings almost three times higher than those of Green Heat. Some factors may explain this gap, including a fundamentally different approach, metering of heat pumps with higher efficiency, as well as the behavioural patterns of participants which were early adopters of heat pumps.

Given that the electrical energy savings results found in the literature are in the same order of magnitude as those found for Green Heat participants who installed MSHPs, especially for the more recent and complete studies, the literature review reinforces the Evaluator's confidence in the results of the billing analysis.

# APPENDIX XXV

## Green Heat 2024 Recommendations

This appendix summarizes all the recommendations made by the Evaluator as part of the 2024 Green Heat evaluation.

| Section           | Recommendations                                                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Executive Summary | Recommendation #1: In light of their very low savings and considering their low uptake, consider removing wood fireplace inserts and pellet fireplace inserts from the Green Heat offer. |

## APPENDIX XXVI

## Introduction

We at Narrative Research are performing an evaluation of energy efficiency services provided by Efficiency Nova Scotia. Our records indicate that you or your household recently participated in the **<INSERT PROGRAM NAME>** program.

We would appreciate your help in answering a very short survey about this program, it will take perhaps 2 or 3 minutes.

**[IF GH]:** As a reminder, the program provides a rebate for the installation of home heating equipment such as **<INSERT MEASURE >**.

**[IF HEA]:** As a reminder, this program involves having an energy advisor conduct an assessment of your home, including a blower door test, and provide participants with energy efficiency upgrade recommendations. THE FEDERAL CANADA GREENER HOMES GRANT INITIATIVE IS DELIVERED WITH EFFICIENCY NOVA SCOTIA THROUGH THE HOME ENERGY ASSESSMENT (HEA) PROGRAM, SO YOU MAY INSTEAD RECALL PARTICIPATING IN THE GREENER HOMES PROGRAM.]

### A. Verification and Recall

A1. We understand you participated in the **<INSERT PROGRAM>** program in **<PARTICIPATION YEAR>** for your house located at **<ADDRESS>** **[IF GH, ADD]** BY INSTALLING A **<INSERT MEASURE>**. Is that correct?

1. Yes **[CONTINUE]**
2. No **[END]**

### B. Verification of Actions Taken

The following questions concern **<IF PROGRAM=HEA>** “the energy efficiency upgrades” **<IF PROGRAM=GH>** “the **<INSERT MEASURE >** installation project” **<FOR ALL>** that you completed through your participation in **<INSERT PROGRAM>** in **<PARTICIPATION YEAR>** for the house located at **<ADDRESS>**

B1. **<IF PROGRAM=HEA>** “Were your energy efficiency upgrades” **<IF PROGRAM=GH>** “Was your **<INSERT MEASURE>**”, **<FOR ALL>** installed as part of a renovation project that involved adding floor area to your home? By adding floor area, we mean that you added an extension to your home, such as a new floor or a new room that was not there before your renovation project.  
**PROGRAM B1 AND B2 AS MANDATORY, ALL OTHER QUESTIONS (EXCEPT A1) WILL BE PROGRAMMED AS OPTIONAL**

1. Yes
2. No

- B2. <IF PROGRAM=HEA>, “Were your energy efficiency upgrades” <IF PROGRAM=GH> “Was your <INSERT MEASURE>” <FOR ALL> installed as part of a renovation project that involved heating rooms that were previously not heated or were only minimally heated (for example,. at a temperature lower than 15°C)? Examples of such renovation projects would be that, you finished your basement and started heating it, or you could have changed a sunroom so that it became heated throughout the year whereas it previously was not.
1. Yes, *the renovation project involved* heating rooms that were previously not heated/were minimally heated
  2. No *the renovation project did not involve* heating rooms that were previously not heated/were minimally heated
- B3. <IF PROGRAM=HEA OR MEASURE=HEAT PUMP>Did you have a fireplace or wood stove in your home <IF PROGRAM=HEA> “before having your home evaluated by an energy advisor” <IF PROGRAM=GH> “before installing your heat pump”? **ACCEPT MULTIPLE ‘YES’ RESPONSE**
1. Yes, a fireplace
  2. Yes, a wood stove
  3. No
- B4. **[IF B3= 1 AND/OR 2]** How, if at all, did usage of your [a. ‘fireplace’ / b. ‘wood stove’] change after you installed your energy efficiency upgrades? Did your usage ...: **[READ – POSE SEPARATELY FOR ‘A’ AND ‘B’, IF 1 AND 2 SELECTED IN B3]**
1. Increase a lot
  2. Increase a little
  3. Stay the same
  4. Decrease a little
  5. Decrease a lot
  6. Did not notice a change
- B5. **[ASK IF PROGRAM=HEA]** Through the <INSERT PROGRAM>, have you installed any type of heat pump, including mini-split, central or geothermal?
1. Yes
  2. No
- B6. **[ASK IF B5=1 OR PROGRAM=GH AND MEASURE=HEAT PUMP]** Prior to INSTALLING YOUR HEAT PUMP, DID YOU ALREADY HAVE A WORKING AIR CONDITIONER IN YOUR HOME? **[DO NOT READ RESPONSES]**
1. Yes
  2. No

END: Thank you for completing today’s survey – your help is greatly appreciated.

## APPENDIX XXVII

### HEA Past Participant Survey Results

**Table B1:** Were your energy efficiency upgrades installed as part of a renovation project that involved adding floor area to your home? By adding floor area, we mean that you added an extension to your home, such as a new floor or a new room that was not there before your renovation project.

| OVERALL %              |            |
|------------------------|------------|
| <b>SAMPLE SIZE (#)</b> | <b>483</b> |
| Yes                    | 2%         |
| No                     | 98%        |

**TABLE B2:** Were your energy efficiency upgrades installed as part of a renovation project that involved heating rooms that were previously not heated or were only minimally heated (for example, at a temperature lower than 15°C)? Examples of such renovation projects would be that, you finished your basement and started heating it, or you could have changed a sunroom so that it became heated throughout the year whereas it previously was not.

| OVERALL %                                                                                                      |            |
|----------------------------------------------------------------------------------------------------------------|------------|
| <b>SAMPLE SIZE (#)</b>                                                                                         | <b>483</b> |
| Yes, the renovation project involved heating rooms that were previously not heated/were minimally heated       | 11%        |
| No, the renovation project did not involve heating rooms that were previously not heated/were minimally heated | 89%        |

**TABLE B3:** Did you have a fireplace or wood stove in your home before having your home evaluated by an energy advisor?

| OVERALL %              |            |
|------------------------|------------|
| <b>SAMPLE SIZE (#)</b> | <b>483</b> |
| Yes, a fireplace       | 21%        |
| Yes, a wood stove      | 30%        |
| No                     | 52%        |

**TABLE B4a:** [IF B3=1] How, if at all, did usage of your fireplace change after you installed your energy efficiency upgrades? Did your usage ...:

| OVERALL %               |     |
|-------------------------|-----|
| SAMPLE SIZE (#)         | 101 |
| Increase a lot          | 2%  |
| Increase a little       | 2%  |
| Stay the same           | 40% |
| Decrease a little       | 16% |
| Decrease a lot          | 16% |
| Did not notice a change | 23% |
| Don't know/No answer    | 2%  |

## Introduction

Could I please speak with <INSERT NAME>?

1. Yes **[GO TO INTRODUCTION]**
2. No **[SAY “PERHAPS YOU CAN HELP ME ANYWAY.” GO TO INTRODUCTION]**

Hello, my name is \_\_\_\_\_ calling on behalf of Narrative Research, a Halifax-based survey research company. We are performing an evaluation of energy efficiency services provided by Efficiency Nova Scotia. Our records indicate that, as part of the Home Energy Assessment program, in < MONTH / YEAR> an Energy Advisor came to your home located at <ADDRESS> to conduct an energy assessment of your home.

We would appreciate your help in answering questions about this program. The information you provide will be used to help Efficiency Nova Scotia improve the program. Is this a good time for you?

**[IF NEEDED: IN NOVA SCOTIA, THE FEDERAL CANADA GREENER HOMES GRANT INITIATIVE IS CO-DELIVERED WITH EFFICIENCY NOVA SCOTIA THROUGH THE HOME ENERGY ASSESSMENT (HEA) PROGRAM. YOU MAY RECALL PARTICIPATING IN THE GREENER HOMES PROGRAM.]**

**[IF NEEDED: The survey will take about five to six minutes.]**

### A. Verification and Recall

A1. Just to confirm, do you recall having an Energy Advisor from a delivery partner of the Home Energy Assessment program come to your home located at <ADDRESS> to complete a home energy assessment in <MONTH / YEAR>?

1. Yes **[CONTINUE]**
2. No **[END]**
- 98.** Don't know **[END]**
- 99.** Refused **[END]**

A2. And do you recall receiving a Home Energy Assessment report that identified renovations or upgrades that could improve your home's energy efficiency?

1. Yes **[CONTINUE]**
2. No **[END]**
- 98.** Don't know **[END]**
- 99.** Refused **[END]**

A3. After reviewing the report, did you complete any of the recommended renovations or upgrades?

1. Yes **[CONTINUE]**
2. No **[END]**
- 98.** Don't know **[END]**
- 99.** Refused **[END]**

A4. To the best of your knowledge, did your household book a follow-up visit where an Energy Advisor would have come back to your home and performed a final energy assessment to see if you qualified for a rebate?

1. Yes [END]
2. No [CONTINUE]
98. Don't know [END]
99. Refused [END]

A5. Do you still live in the home located at <ADDRESS>?

1. Yes [CONTINUE]
2. No [END]
98. Don't know [END]
99. Refused [END]

## B. Upgrades Implemented and Influence

B1. Which of the following upgrades, if any, did you implement after you received your home energy assessment report? [DO NOT ROTATE - CODE ONE ONLY PER STATEMENT]

[1 = YES, IMPLEMENTED, 2 = NO, NOT IMPLEMENTED, 3 = ALREADY HAD INSTALLED, 4 = THAT UPGRADE WAS NOT SUGGESTED IN THE REPORT, 98 = DON'T KNOW / DON'T REMEMBER, 99 = REFUSED] [READ]

- a. Install any type of heat pump, including mini-split, central or geothermal
- b. Install insulation including attic, ceiling, exterior wall, exposed floor, basement, crawlspace, or foundation insulation
- c. Install new windows, doors or skylights
- d. Install an efficient ventilation system (heat recovery ventilation system)
- e. Install air sealing or draft proofing
- f. Install a heat pump water heater
- g. Install a wood or pellet stove or furnace
- h. Install a smart thermostat
- i. Install solar PV system

B2. [ASK IF B1A=1] Did you apply for a rebate for your heat pump through another program?

1. Yes
2. No
98. Don't know
99. Refused

- B3. **[POSE B3 ONLY IF 'YES' TO ONE OR MORE ITEMS IN B1a-i]** To what extent, if at all, did your home energy assessment report influence your decision to proceed with the upgrades you implemented? Please give your answer on a scale of 0 to 10, where 0 indicates that the home energy assessment “had no influence at all” and 10 indicates that the assessment “had a great deal of influence”.

**[0-10 SCALE WITH END POINT LABELS – RECORD NUMBER]**

## **C. Reasons for Not Conducting an E Assessment**

- C1. Which one of the following best describes the reason why you chose not to have the follow-up visit by an Energy Advisor? **[DO NOT READ, ACCEPT ONE RESPONSE]**

1. Follow-up visit was too difficult to schedule
2. Follow-up visit was too expensive
3. Follow-up visit takes too long
4. I was too busy / I did not have time
5. I don't believe the results of the visit would be useful, relevant or accurate
6. The follow-up visit was unnecessary because the work to save energy was already done
7. Didn't book a follow-up visit because we didn't intend to undertake the recommended upgrades
96. Other [SPECIFY\_\_\_\_\_]
- 98. Don't know [GO TO NEXT SECTION]**
- 99. Refused [GO TO NEXT SECTION]**

- C2. Were there other reasons as well? **[DO NOT READ, ACCEPT ALL RESPONSES]**

1. Follow-up visit was too difficult to schedule
2. Follow-up visit was too expensive
3. Follow-up visit takes too long
4. I was too busy / I did not have time
5. I don't believe the results of the visit would be useful or accurate
6. The follow-up visit is unnecessary because the work to save energy is already done
7. Didn't book a follow-up visit because we haven't completed many of the recommended upgrades
8. No other reason
96. Other [SPECIFY\_\_\_\_\_]
- 98. Don't know**
- 99. Refused**

## **D. Verification of Interest for a Visit**

D1. Would you be interested in having an Energy Advisor again come to your home, for free, to perform an energy assessment of your house?

1. Yes

2. No

**98.** (Don't know)

**99.** (Refused)

**END:** Those are all the questions I have for you. Thank and terminate.

## APPENDIX XXIX

### HEA Expired Participant Survey Results

**TABLE A1:** Just to confirm, do you recall having an Energy Advisor from a delivery partner of the Home Energy Assessment program come to your home located at <ADDRESS> to complete a home energy assessment in <MONTH / YEAR>?

| OVERALL %              |            |
|------------------------|------------|
| <b>SAMPLE SIZE (#)</b> | <b>338</b> |
| Yes                    | 97%        |
| No                     | 2%         |
| Don't know             | 1%         |
| Refused                | 0%         |

**TABLE A2:** [POSE ONLY IF 'YES' TO A1] And do you recall receiving a Home Energy Assessment report that identified renovations or upgrades that could improve your home's energy efficiency?

| OVERALL %                                                                         |            |

## APPENDIX XXX

### HEA Tracking Sheet Audit

This appendix presents the main results of the tracking sheet audit performed by the Evaluator, which was aimed at:

- › Verifying that all data fields required for the evaluation were included and filled out in the tracking sheet submitted by E1
- › Ensuring that tracked results were accurate by:
  - › Verifying that parameters used to calculate program results (gross and net electrical energy and peak demand savings at the generator) were consistent with previous evaluation results
  - › Validating that all calculation steps were performed consistently

Table 1 presents the corrected tracked savings resulting from all changes made by the Evaluator.

**Table 1: 2024 HEA Corrected Tracked Savings**

| Program Component Results                  | Value Tracked by E1 |      | Corrected Tracked Value |      | Relative Difference |
|--------------------------------------------|---------------------|------|-------------------------|------|---------------------|
|                                            | Value               | Unit | Value                   | Unit | Value               |
| <b>HEA</b>                                 |                     |      |                         |      |                     |
| Gross Energy Savings at the Generator      | 42.057              | GWh  | 41.992                  | GWh  | -0.15%              |
| Gross Peak Demand Savings at the Generator | 10.399              | MW   | 10.518                  | MW   | 1.14%               |
| Net Energy Savings at the Generator        | 29.740              | GWh  | 29.552                  | GWh  | -0.63%              |
| Net Peak Demand Savings at the Generator   | 5.352               | MW   | 5.367                   | MW   | 0.28%               |

The differences between the tracked and corrected values are mainly explained by the following corrections made by the Evaluator.

- › **For the differences in gross energy savings:**
  - › Correction of unitary savings for some biomass measures
  - › Correction of the logic used to determine the unitary savings for HPWH (heat pump or electric baseboard baseline heating system)
- › **For the differences in net energy savings:**
  - › Correction of NTGR and/or line loss factors for some participants that had hardcoded values using outdated parameters instead of formulas
  - › A deduction of additional participants for unconverted D assessment spillover reversals
  - › Correction of Green Heat savings deductions. In the 2024 Summary tab of the tracking sheet, EfficiencyOne uses hardcoded values instead of a calculation referencing the tracking sheet; the Green Heat savings deductions correspond to the gross savings at the meter, whereas it should have been net savings at the generator

› **For the differences in demand savings:**

- › The same explanations as for energy savings
- › Correction of formula for biomass measures, which rounded the savings at the kW instead of the W for each participant
- › Correction of some heat pump specifications based on cross-reference with NEEP list.

## APPENDIX XXXI

# HEA Detailed Billing Analysis Methodology and Results

---

### Background

After inconclusive results in 2023, a billing analysis was again conducted for HEA as part of the 2024 DSM evaluation to obtain measured electrical energy savings generated through the installation of energy efficiency upgrades. **Instead of calculating overestimation ratios (ORs) to be applied to pre and post-space heating consumption obtained from HOT2000**, as is the case in the current savings calculation approach, **the Evaluator used the savings values obtained through the AMI data to develop adjustment ratios (ARs) that can be directly applied to the modelled savings estimates obtained from HOT2000 using whole home consumption** (not only space heating).

The main reasons for recommending a change in the current savings calculation approach are as follows:

- › A higher proportion of participants use a heat pump for heating since the ORs currently used in the savings calculation were determined. The use of a heat pump instead of electrical baseboards makes it more difficult to isolate space heating consumption as the linear correlation with heating degree days is less significant. With the current savings calculation methodology, space heating consumption needs to be isolated because the ORs are calculated specifically for space heating.
- › The complexity of the HEA savings calculation approach is increasing, and the use of ARs directly applied to the savings value (instead of the D and E assessment consumption values separately) simplifies the calculation.

Unlike the billing analysis conducted in 2023, **AMI data**, which started to be progressively available for residential customers in 2020, were used for the 2024 billing analysis.

### Methodology

To assess the electrical energy savings obtained from HEA energy efficiency upgrades, the billing analysis consisted of calculating the change in electrical energy consumption before (pre) and after (post) participation in HEA for a group of recent participants (treatment group). To account for variations in electrical energy consumption due to factors other than HEA participation, the Evaluator selected a control group and deducted the change in electrical energy consumption observed for that group over the same period. Subtracting the change in control group electrical energy consumption (i.e. a change that is not linked to the program component) from that of the treatment group ensures that **only savings attributable to HEA changes are captured and avoids capturing other effects that can have an impact on energy consumption** (e.g. the COVID-19 pandemic) because both the treatment and control groups are impacted by those effects.

Once the electrical energy savings are obtained from the AMI data, they are normalized and compared with the modelled savings values obtained from HOT2000 to establish average **ARs**.

The following subsections detail how the AMI data were used to calculate the electrical energy savings and ultimately the adjustment ratios.

## Selection of the Treatment and Control Groups

The initial treatment group included 1,803 HEA participants who were selected based on the following criteria:

- › Be 100% electrically heated according to HOT2000 (meaning that the primary heating system is electrical and there is no secondary heating system using other fuels and whose consumption is modelled in HOT2000, although the house can still have a supplementary heating system in place such as a fireplace or wood stove whose consumption is not modelled in HOT2000)
- › Have an E assessment date before September 2023 to ensure a full year of post data
- › Have a D assessment date no earlier than November 2021 to avoid overlap with control group participation
- › Did not install wood/pellet equipment or solar PV as part of their participation in HEA
- › Use HOT2000 version 11.10 or later version

Among the 1,803 participants selected based on these criteria, AMI data were available for 1,322 participants. The main reason is because NS Power account numbers were not available for all participants; hence, EfficiencyOne had to match the names and addresses, which was not conclusive for all participants.<sup>6</sup> In addition, some participants were not NS Power customers.

The initial control group included a total of 1,227 customers who were selected based on the following criteria:

- › Be 100% electrically heated according to HOT2000 (same details as for treatment group above)
- › Have participated in HEA before those in the treatment group, i.e. who had an E assessment date between January 2019 and November 2020
- › Use any HOT2000 version (the version used is not important for control group customers considering that only the post-program participation period is looked at for control group customers and only the consumption listed in their electrical bills is used, not the modelled consumption. This means that the version of HOT2000 used to model control group household consumption has no impact on the analysis. The control group is only used to deduct any change in consumption that is not attributable to HEA from the change observed in the treatment group consumption data.)

Among the 1,227 participants selected based on these criteria, AMI data were available for 1,018 participants.<sup>7</sup>

By selecting the control group among a sample of past HEA participants, the Evaluator ensures that control group participants have similar characteristics to treatment group participants, as recommended for matched control group approaches in Chapter 8 of the Uniform Methods Project (UMP). The process to match control and treatment participants is further described below.

## AMI Data Preparation

AMI data for treatment group and control group participants were obtained from two sources:

- › NS Power for the period between the moment AMI data became available (2020) and November 2023
- › EfficiencyOne for the year 2024 (in May 2023, EfficiencyOne started to have access to AMI data in the NS Power system)

In both cases, the AMI data were aggregated on a monthly basis.

---

<sup>6</sup> The Evaluator kept only participants with a high level of confidence in the NS Power data matching in the analysis.

<sup>7</sup> As it was the case for the treatment group, the Evaluator kept only participants with a high level of confidence in the NS Power data matching in the analysis.

Before performing the billing analysis, the Evaluator validated the consumption load shapes for each treatment and control group participant to exclude those participants with inconsistent consumption data. Data that matched the following criteria were excluded:

- › Nil consumption or missing data in the study period
- › Very high or very low peaks in the study period
- › Numerous abnormal variations in the consumption pattern (extremely high consumption months followed by close to zero consumption for instance)

After excluding the data that matched the above criteria, about 5% of the sample was excluded.

Similar criteria were applied to the control group customers, and the sample remained largely sufficient to have a different match for each treatment group participant.

### Control-Treatment Participant Matching

To determine the best suited control group participant for each treatment group participant, the Evaluator first applied a set of minimum conditions with which to comply:

- › The E assessment date of the control participant must be at least one year before the D assessment date of the treatment participant.
- › The weather station must be the same.
- › The heating type (with or without a heat pump) after the E assessment must be the same.

These conditions left treatment participants with more than one potential control participant. The point system presented in Table 1 below was then used to provide a score for each potential control participant. The control participant with the highest score was then considered the ideal match and was assigned to the given treatment participant.

**Table 1: Details on the Point System Used for the Selection of Control Participants**

| Parameters                                                                              | Points                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Average annual consumption of treatment and control candidates after their E assessment | Add a maximum of 2 points based on a function of the relative difference between the average annual consumption of treatment and control candidates using a sigmoid function that yields approximately the following points: <ul style="list-style-type: none"><li>› 2 points if difference is 10%</li><li>› 1 point if difference is 25%</li><li>› 0 points if difference is 50% or more</li></ul> |

It should be noted that each participant has different pre and post-program periods based on when participation in HEA occurred. Given this, each treatment group participant was assigned one control group participant, and the dates of the pre and post-periods of treatment participants were applied to the control participants for this match.

### Weather Normalization

The Evaluator normalized the consumption values obtained from the AMI data using normal weather data to obtain annual consumption values that are aligned with a typical meteorological year. A regression was used to determine how consumption related to heating and cooling degree days was associated with the weather station and billing dates of each control and treatment participant. Multiple iterations were made to select the most appropriate balance temperature to calculate the heating and cooling degree days.

Then, the normal heating and cooling degree days were included in each regression to obtain energy consumption during a typical weather year. The Evaluator calculated the normal heating and cooling degree days based on the previous 15 years (2008-2023) for the five weather stations selected for the analysis (Debert, Greenwood, Halifax, Sydney, and Yarmouth).

### Energy Savings Calculation

Figure 1 below illustrates how energy savings were obtained by calculating the difference in the treatment group normalized annual consumption of each participant for the year before and after program participation and deducting the difference observed in the control group normalized annual consumption for the same period as the treatment participant to which the control participant was assigned.

**Figure 1: Energy Savings Calculation Using AMI Data**

- › T\_Pre: Normalized annual consumption of the treatment participant for the year before the D assessment
- › T\_Post: Normalized annual consumption of the treatment participant for the year after the E assessment
- › C\_Pre: Normalized annual consumption of the assigned control participant for the year before the D assessment of the assigned treatment participant
- › C\_Post: Normalized annual consumption of the assigned control participant for the year after the E assessment of the assigned treatment participant

Then, the energy savings were divided by the savings values obtained from HOT2000 to establish adjustment ratios using the following equation.

$$\text{Adjustment Ratio (AR)} = \frac{\text{Energy Savings}}{\text{Modelled HOT2000 Savings}}$$

$$\text{Modelled HOT2000 Savings} = \text{Total Elec}_D - \text{Total Elec}_E$$

Considering that only participants who implemented modelled measures were included in the treatment group, the ARs are not impacted by the electrical energy savings associated with the installation of wood burning equipment or solar PV systems, which are claimed using prescriptive savings. In addition, no treatment group participants had installed HPWHs, which are also deducted from the calculation and claimed separately using prescriptive savings as presented in the Energy Savings subsection of the HEA evaluation report.

## Detailed Results

Once the main steps of the billing analysis were completed, the Evaluator conducted several analyses to interpret the data. The three scenarios used to establish ORs, associated with the presence of a heat pump or not, remain the most relevant.

The results of the past participant survey were used to remove participants who added heating to existing rooms or floor area. According to survey results, more than one in ten participants declared having added heating or floor area. The analysis of their pre and post-consumption data shows much lower savings than those obtained for participants who did not add heating or floor area, which demonstrates that the addition of heating or floor area has an impact that should be taken into account to avoid capturing an increase in consumption that should not be attributable to the program component.

While analyzing the past participant survey results, Econoler also noticed important variations in some of the pre and post-consumption values of the control group paired with the treatment participants in the survey sample, while the variations were much smaller when looking at the entire control group. Therefore, Econoler concluded that using the average consumption values of the entire control group would be more representative of the average fluctuations in energy consumption that should be deducted from the treatment group.

The following table presents the results from the analysis for each heat pump scenario.

**Table 2: Detailed Results from the Analysis by Heat Pump Scenario**

| Scenario                                                                                   | Sample Size | Pre-consumption (kWh/year) | Post-consumption (kWh/year) | Difference (kWh/year) |
|--------------------------------------------------------------------------------------------|-------------|----------------------------|-----------------------------|-----------------------|
| <b>A participant who registered with a heat pump</b>                                       |             |                            |                             |                       |
| Treatment Group                                                                            | 49          | 20,245                     | 17,014                      | 3,231                 |
| Control Group                                                                              | 341         | 17,479                     | 16,934                      | 545                   |
| <b>A participant who registered without a heat pump and then had one installed</b>         |             |                            |                             |                       |
| Treatment Group                                                                            | 86          | 17,913                     | 14,376                      | 3,537                 |
| Control Group                                                                              | 557         | 15,845                     | 15,423                      | 422                   |
| <b>A participant who registered without a heat pump and who did not have one installed</b> |             |                            |                             |                       |
| Treatment Group                                                                            | 7           | 16,953                     | 14,207                      | 2,746                 |
| Control Group                                                                              | 27          | 17,163                     | 17,041                      | 122                   |

The resulting ARs with their margins of error are presented in the following table. The relatively high margins of error are a result of the high variability in the savings values and the limited sample due to the fact that survey results were used to isolate participants who did not add heating in existing rooms or floor area. Despite that, the Evaluator considers the ARs reliable considering the consumption trends are consistent.

**Table 3: Evaluated Adjustment Ratios by Heat Pump Scenario**

| Scenario                                                                                   | AR   | Margin of Error |
|--------------------------------------------------------------------------------------------|------|-----------------|
| A participant who registered <b>with</b> a heat pump                                       | 1.24 | 57.7%           |
| A participant who registered <b>without</b> a heat pump and who did not have one installed | 0.58 | 13.2%           |
| A participant who registered <b>without</b> a heat pump and then had one installed         | 0.43 | 93.0%           |

## MSHPs Savings

Since the billing analysis was conducted simultaneously for HEA and Green Heat, the Evaluator also compared the MSHP savings measured for Green Heat to those measured for HEA participants who only installed heat pumps (so that savings from other measures such as building envelope improvements would not be considered). On average, HEA participants who only installed heat pumps saved 2,459 kWh, while Green Heat participants saved 1,177 kWh. These numbers are not directly comparable because the systems installed in HEA and Green Heat differ. When looking at the savings per capacity installed, they are much closer (0.0760 kWh/Btu/h for HEA versus 0.0666 kWh/Btu/h for Green Heat). Indeed, the average capacity of HEA heat pumps is 32 kBtu/h for participants who only installed a MSHPs compared to just over 17 kBtu/h for Green Heat.

## Impacts of Billing Analysis Results on Modelled Measure Savings

To get a sense of how the new adjustment ratios and calculation approach impact energy savings for modelled measures in HEA, Table 4 below compares gross electrical energy savings at the meter with and without ratios for all modelled measures for 2024. Overall, the new adjustment ratios and calculation approach are slightly more penalizing than the overestimation ratios and previous calculation approach.

**Table 4: HOT2000 Modelled Measure Gross Electrical Energy Savings at the Meter for 2024**

|                                                                                                                                                                                                                                                                                                                                                                      | Corrected Tracked<br>Energy Savings<br>(Overestimation Ratio) | Evaluated<br>Energy Savings<br>(Adjustment Ratio) |

| Gross Energy Savings at the Meter, Without Ratio (GWh)*                                                                                                                                                                                                                                                                                                              | 15.402                                                        | 14.062                                            |
| Gross Energy Savings at the Meter, with Ratio (GWh)                                                                                                                                                                                                                                                                                                                  | 11.684                                                        | 9.200                                             |
| <b>Overall De-rating of HOT2000 Modelled Measures (%)</b>                                                                                                                                                                                                                                                                                                            | <b>24%</b>                                                    | <b>35%</b>                                        |
| *Gross energy savings at the meter without ratios applied differ between corrected tracked and evaluated because of differences in the calculation approach (i.e. the new calculation methodology uses electrical energy consumption of the whole home, whereas the previous methodology used only the electrical energy consumption associated with space heating). |                                                               |                                                   |

## APPENDIX XXXII

### HEA Reporting Requirements

---

HEA incentives originate from three sources of funding and are thus reported to different parties via the DSM evaluation and government-funded evaluation. The DSM evaluation is focused on reporting electrical savings funded by electrical DSM funds, while the government-funded evaluation is focused on participation and GHG emission reductions generated from government funding regardless of the type of fuel. To avoid double counting and determine the most appropriate way to report savings, EfficiencyOne developed the equations and rationales presented in Table 1 below.

The equations presented in Table 1 were used in the tracking sheet for all participants who implemented building envelope measures or installed new space heating equipment. The equations were updated in 2019 to better reflect both the energy savings associated to fuel switching (i.e. from fossil fuel space heating energy sources to electrical heat pumps or wood burning equipment) and the distribution of savings between DSM-funded and government-funded programs for households that use multiple energy sources. The incorporation of the Canada Greener Homes Grant in 2021, as a co-funder of energy assessments and measures for both DSM and government funding, has not changed anything in the reporting structure. In 2024, the equations were updated to reflect the change in the overall savings calculation methodology, although no changes were made to the distribution of savings between DSM-funded and government-funded programs itself.

When a fuel switch occurred from a non-electrical heating system in the D assessment to an electrical heating system in the E assessment, electrical savings were capped at 0 kWh and the overall savings, taking into account the increase in electrical consumption, were claimed as non-electrical savings.

The equations reference the following parameters:

- › Total electrical energy consumption ( $\text{Elec\_Consumption}_D$  and  $\text{Elec\_Consumption}_E$ ) obtained from HOT2000 during the D and E assessments
- › Total energy consumption ( $\text{Total\_Consumption}_D$  and  $\text{Total\_Consumption}_E$ ) obtained from HOT2000 during the D and E assessments
- › Savings from wood burning equipment that are not modelled in HOT2000 (wood savings). These savings are reported in either the HEA DSM evaluation report or government-funded evaluation report, or a combination of both depending on the percentage of space heating from electrical sources at the E assessment ( $\text{Percent\_ElecHeating}_E$ ).
- › Savings from HPWHs (HPWH savings). These savings are reported in either the HEA DSM evaluation report or government-funded evaluation report depending on the baseline DHW heating system energy source.

It should be noted that solar PV measures are excluded from these equations. All solar PV measures are claimed in the DSM evaluation report as they offset electricity use.

**Table 1: Reporting Requirements for Different Energy Savings Scenarios<sup>8</sup>**

| Scenarios                                            | 1                                   | 2                                                                                                                                                                                                                                              | 3                                                                                                                                                                                                                                                  | 4                                                                                                                                                                          |
|------------------------------------------------------|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Change in Overall Electrical Energy Consumption      | Increase                            | Increase                                                                                                                                                                                                                                       | Decrease                                                                                                                                                                                                                                           | Decrease                                                                                                                                                                   |
| Change in Overall Non-electrical Energy Consumption  | Increase                            | Decrease                                                                                                                                                                                                                                       | Decrease                                                                                                                                                                                                                                           | Increase                                                                                                                                                                   |

| Equation Used to Calculate DSM Savings               | N/A                                 | $\text{Percent\_ElecHeating}_E * \text{Wood Savings} + \text{HPWH Savings (if baseline DHW = electric)}$                                                                                                                                       | $\text{Electric\_Consumption}_D - \text{Electric\_Consumption}_E + \text{Percent\_ElecHeating}_E * \text{Wood Savings} + \text{HPWH Savings (if baseline DHW = electric)}$                                                                         | $\text{Electric\_Consumption}_D - \text{Electric\_Consumption}_E + \text{Percent\_ElecHeating}_E * \text{Wood Savings} + \text{HPWH Savings (if baseline DHW = electric)}$ |
| Equation Used to Calculate Government-funded Savings | N/A                                 | $\text{Total\_Consumption}_D - \text{Total\_Consumption}_E - (\text{Electric\_Consumption}_D - \text{Electric\_Consumption}_E) + (1 - \text{Percent\_ElecHeating}_E) * \text{Wood Savings} + \text{HPWH Savings (if baseline = non-electric)}$ | $\text{Total\_Consumption}_D - \text{Total\_Consumption}_E - (\text{Electric\_Consumption}_D - \text{Electric\_Consumption}_E) + (1 - \text{Percent\_ElecHeating}_E) * \text{Wood Savings} + \text{HPWH Savings (if baseline DHW = non-electric)}$ | $(1 - \text{Percent\_ElecHeating}_E) * \text{Wood Savings} + \text{HPWH Savings (if baseline DHW = non-electric)}$                                                         |
| Rationale                                            | This situation never occurs in HEA. | These projects are government-funded with no DSM funding.                                                                                                                                                                                      | The savings are included in the appropriate report based on the equations above. DSM savings are subtracted from government-funded savings to avoid double counting.                                                                               | These projects are entirely DSM-funded with no government funding                                                                                                          |

<sup>8</sup> To simplify the equations in Table 1, adjustment ratios are omitted.

## APPENDIX XXXIII

### HEA 2024 Recommendations

---

This appendix summarizes all the recommendations made by the Evaluator as part of the 2024 HEA evaluation.

| Section           | Recommendations                                                                                                                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Executive Summary | Recommendation #1: In light of their very low savings and considering their low uptake, consider removing wood fireplace inserts and pellet fireplace inserts from the HEA offer. |

## APPENDIX XXXIV

### MHEEP Tracking Sheet Audit

This appendix presents the main results of the tracking sheet audit performed by the Evaluator, which was aimed at:

- › Verifying that all data fields required for the evaluation were included and filled out in the tracking sheet submitted by E1
- › Ensuring that tracked results were accurate by:
  - › Verifying that parameters used to calculate program results (gross and net energy and peak demand savings at the generator) were consistent with previous evaluation results
  - › Validating that all calculation steps were performed consistently

Table 1 presents the corrected tracked savings resulting from all changes made by the Evaluator.

**Table 1: 2024 MHEEP Corrected Tracked Savings**

| Program Component Results                       | Value Tracked by E1 |      | Corrected Tracked Value |      | Relative Difference |
|-------------------------------------------------|---------------------|------|-------------------------|------|---------------------|
|                                                 | Value               | Unit | Value                   | Unit | Value               |
| <b>MHEEP (Excluding Appliance Replacements)</b> |                     |      |                         |      |                     |
| Gross Energy Savings at the Generator           | 0.572               | GWh  | 0.572                   | GWh  | 0.00%               |

| Net Energy Savings at the Generator             | 0.572               | GWh  | 0.572                   | GWh  | 0.00%               |
| Net Peak Demand Savings at the Generator        | 0.402               | MW   | 0.419                   | MW   | 4.16%               |
| <b>Appliance Replacements</b>                   |                     |      |                         |      |                     |
| Gross Energy Savings at the Generator           | 0.005               | GWh  | 0.006                   | GWh  | 15.90%              |
| Gross Peak Demand Savings at the Generator      | 0.001               | MW   | 0.001                   | MW   | 13.30%              |
| Net Energy Savings at the Generator             | 0.005               | GWh  | 0.006                   | GWh  | 15.90%              |
| Net Peak Demand Savings at the Generator        | 0.001               | MW   | 0.001                   | MW   | 13.30%              |
| <b>MHEEP Total</b>                              |                     |      |                         |      |                     |
| Gross Energy Savings at the Generator           | 0.577               | GWh  | 0.578                   | GWh  | 0.14%               |
| Gross Peak Demand Savings at the Generator      | 0.403               | MW   | 0.420                   | MW   | 4.18%               |
| Net Energy Savings at the Generator             | 0.577               | GWh  | 0.578                   | GWh  | 0.14%               |
| Net Peak Demand Savings at the Generator        | 0.403               | MW   | 0.420                   | MW   | 4.18%               |

For modelled measures, the tracked and corrected electrical energy savings were equal. The higher corrected peak demand savings compared to the value tracked by E1 were due to a change in methodology by the Evaluator to better account for the percentage of electrical space heating and better align with how that percentage is used in energy savings calculations. The change resulted in a mix of upward and downward adjustments, overall resulting in a small upward adjustment. For non-modelled measures, the differences between the tracked and corrected savings are due to incorrect and older unitary savings having been used by E1 for freezer and refrigerator replacements.

## APPENDIX XXXV

### MHEEP 2024 Recommendations

---

The Evaluator made no specific recommendation as part of the 2024 MHEEP evaluation.

## APPENDIX XXXVI

### Residential Behaviour: Monthly Savings Approach

While they are not used to claim savings, monthly savings were calculated to observe monthly trends and the ramp-up period in more detail. An equation similar to that of the cumulative approach is used for the monthly approach. For a given month, the DiD model serves to **compare the difference in the average daily consumption between the treatment group and the control group before and after program participation**. The equation is expressed as follows.

$$\text{Monthly Savings} = \left[ (Post\_kWh_{Control,m} - Post\_kWh_{Treat,m}) - (Pre\_kWh_{Control,m} - Pre\_kWh_{Treat,m}) \right] \\ \times Households_{TG,m} \times Nb\_Days_m$$

Where:

- ›  $m$  = A number between 1 and 12 to identify the given month
- ›  $Post\_kWh_{Control,m}$  = The control group's average daily consumption in a given month of the post-program period
- ›  $Post\_kWh_{Treat,m}$  = The treatment group's average daily consumption in a given month of the post-program period
- ›  $Pre\_kWh_{Control,m}$  = The control group's average daily consumption in a given month of the pre-program period
- ›  $Pre\_kWh_{Treat,m}$  = The treatment group's average daily consumption in a given month of the pre-program period
- ›  $Households_{Treat,m}$  = The total number of active participating households in the treatment group in a given month
- ›  $Nb\_Days_m$  = The total number of treatment days in a given month

Table 1 below presents the 2024 monthly electricity savings calculated by the Evaluator for the high, medium and low users. Note that the numbers of active treatment participants in May 2024 differ from those presented in Subsection 29.3 from the report, due to accounts that became inactive or switched to solar between the moment the groups were selected and the launch of the program component.

**Table 1: 2024 Residential Behaviour Evaluated Electricity Monthly Energy Savings**

\*For each month, the percentage of monthly savings is calculated by dividing the average daily savings by the average daily consumption of the control group.

\*\* The margins of error were calculated at a 90% confidence level.

\*\*\* The values indicated in red are not statistically significant, meaning that the results for those months are inconclusive and are considered nil.

As depicted in Figure 1, Figure 2, and Figure 3 below, the evolution of the monthly savings values and their margins of error during the first months of the post-program period illustrate a program ramp-up effect. For most months, the margins of errors include zero savings because of this ramp-up effect, meaning that the average savings values for those three months are uncertain and not statistically significant.

With only eight months since program component launch excluding the winter period, analyses of monthly results are limited. The Evaluator notes that wave 1 (high electricity users) presented the highest kWh savings values per participant for the months of October to December and 0.87% of savings achieved in October. Waves 2 and 3 also indicated good potential with savings percentages of 0.81% and 1.07% in October and December respectively.

**Figure 1: 2024 High User Monthly Electricity Savings**

Note: When the confidence interval includes values below zero, the savings are not statistically significant, which is the case for all months except for October and November 2024.

**Figure 2: 2024 Medium User Monthly Electrical Savings**

Note: When the confidence interval includes values below zero, the savings are not statistically significant, which is the case for all months except for October 2024.

**Figure 3: 2024 Low User Monthly Electrical Savings**

Note: When the confidence interval includes values below zero, the savings are not statistically significant, which is the case for all months except for December 2024.

## APPENDIX XXXVII

### Residential Behaviour 2024 Recommendations

---

The Evaluator made no specific recommendation as part of the 2024 Residential Behaviour evaluation.

## DEFINITIONS

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Accuracy</b>                           | Reflects the proximity of measurements to the true value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Adjustment ratio</b>                   | The ratio of evaluated results to tracked results. This ratio expresses the adjustment made to tracked savings or other tracked values such as effective useful life.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Available Demand Response Capacity</b> | The capacity which is available to NSP to reduce system peak demand. This capacity is calculated based on the first two hours of all events called between December and February, excluding weekends and holidays. If an event is shorter than two hours, only the first hour is used to measure the available DR capacity. Available DR capacity is evaluated on a per-participant basis, based on the average demand reduction observed for each event that the participant was scheduled to participate in. E1's total available DR capacity is the sum of each participant's available DR capacity. |
| <b>Baseline</b>                           | To determine gross savings, a baseline (or base case) is established providing detailed information about the reference (e.g. pre-existing or standard) measure or equipment chosen to be compared with the efficient measure or equipment. For the reference measure or equipment, the baseline may include such information as the hours of operation, wattage, and base consumption.                                                                                                                                                                                                                 |
| <b>Bias</b>                               | Systematic deviations of measurements from the true value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Billing calibration</b>                | An activity that consists of adjusting the expected energy savings based on the relative difference between the results of energy simulations and the actual energy consumption of a building or system.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Confidence interval</b>                | The estimated range of values that is likely to include unknown population parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Demand response</b>                    | Demand response measures generate savings in the form of available capacity or load reduction in response to events called by the electric utility (Nova Scotia Power) to reduce the load at strategic moments. These events can be called at any time and for any duration, although they are usually called for one to four hours during peak periods.                                                                                                                                                                                                                                                |
| <b>Displaced wattage</b>                  | The displaced wattage is defined as the difference between the wattage values of the baseline equipment or product and the efficient equipment or product.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>EnerGuide rating</b>                   | An EnerGuide (official brand of Natural Resources Canada) rating is a standard measure of home energy performance. It is a measure of the efficiency of the building only and does not take into account occupant behaviour. It shows how energy efficient a home is through modelled home heat losses based on several factors including building envelope characteristics, heated volume, heating systems, and air leakage.                                                                                                                                                                           |
| <b>Effective useful life</b>              | The period a measure is expected to be in service and provide both energy and peak demand savings. This value combines equipment life and measure persistence, which includes factors such as business turnover or early retirement.                                                                                                                                                                                                                                                                                                                                                                    |

|                                         |                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Equipment life</b>                   | The number of years installed equipment will operate before it fails.                                                                                                                                                                                                                                                |
| <b>Equivalent CO2</b>                   | A unit of measurement indicating the amount of carbon dioxide to which various kinds of emitted greenhouse gases are equivalent in terms of warming effects. In this report, gas global-warming potential is estimated over a timescale of 100 years.                                                                |
| <b>Equivalent effective useful life</b> | The number of years by which the first-year savings estimate is multiplied to obtain lifetime energy savings. This value takes into account variations in annual energy savings throughout the effective useful life due to increased baselines.                                                                     |
| <b>Evaluated savings</b>                | Gross and net energy or peak demand savings calculated by the Evaluator using the parameters (unitary savings values, installation rates, interactive effects, net-to-gross ratios, etc.) validated or measured during the evaluation process. Unless otherwise specified, evaluated savings are first-year savings. |
| <b>Evaluation plan</b>                  | The evaluation plan summarizes the program description, objectives, base cases, documentation, evaluation methodology, budget, and schedule.                                                                                                                                                                         |
| <b>First-year savings</b>               | The first full year of energy or peak demand savings generated by an energy efficiency measure.                                                                                                                                                                                                                      |
| <b>Free-ridership</b>                   | Percentage of gross savings attributable to participants who would have implemented the same or similar energy efficiency measures, with no change in timing, in the absence of the program.                                                                                                                         |
| <b>Gross savings</b>                    | Change in energy consumption and/or demand that results directly from program-related actions taken by participants in an efficiency program regardless of why they participated.                                                                                                                                    |
| <b>Induced consumption</b>              | Energy consumption of appliances that would have been unplugged and not replaced by participants in the absence of the program.                                                                                                                                                                                      |
| <b>Interactive effects</b>              | Effects on the energy consumption of other systems in a building (such as heating and cooling) due to the installation of an energy-efficient measure.                                                                                                                                                               |
| <b>In-service rate</b>                  | The proportion of incentivized products that are installed and operating. This rate is usually applied to programs through which rebates are offered in-store and products are likely to be stored for a certain period before being installed, such as LED lamps.                                                   |
| <b>Installation rate</b>                | The proportion of incentivized products reported as installed and that remain installed and operating at the time of evaluation. This rate is usually applied to direct install or mail-in rebate programs through which measures are expected to be installed immediately at the time of participation.             |
| <b>Lifetime energy savings</b>          | The energy savings that occur over the lifetime of an energy efficiency measure. Lifetime energy savings account for a measure's effective useful life and any increase in the baseline efficiency level (which reduces attributable annual savings) over its lifetime.                                              |
| <b>Line loss factor</b>                 | The multiplier to convert savings at the customer meter to savings at the utility generator. It accounts for the electrical losses of the transmission and distribution system.                                                                                                                                      |

|                                 |                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Margin of error</b>          | The amount of random sampling error.                                                                                                                                                                                                                                                                                                         |
| <b>Market effects</b>           | The impact of a program on the market (in terms of product availability, practices, and prices) that extends beyond changing program participant behaviours. This includes spillover among non-participants.                                                                                                                                 |
| <b>Net savings</b>              | Energy or peak demand savings that can be reliably attributed to a program. This includes effects such as free-ridership and spillover that negatively or positively affect the savings attributable to a program.                                                                                                                           |
| <b>Net-to-gross ratio</b>       | The ratio of net energy savings to gross energy savings.                                                                                                                                                                                                                                                                                     |
| <b>Non-sampling error</b>       | Errors arising during all survey activities other than sampling. Non-sampling errors tend to lead to bias in measurements and are very difficult to quantify.                                                                                                                                                                                |
| <b>Peak coincidence factor</b>  | The percentage of measure demand savings that coincide in time with the annual peak demand of the entire electricity system.                                                                                                                                                                                                                 |
| <b>Peak demand savings</b>      | The demand savings that coincide in time with the expected annual peak demand period of the entire electricity system. For industrial participants on an interruptible rate, peak demand savings may include savings on non-firm loads, i.e. loads that may be interrupted when Nova Scotia Power's 10-minute reserve is low.                |
| <b>Precision</b>                | The extent to which repeated measurements agree with one another.                                                                                                                                                                                                                                                                            |
| <b>Random sampling error</b>    | An error in measurement because measurements are taken from a subset of the population and not the entire population.                                                                                                                                                                                                                        |
| <b>Realization rate</b>         | The ratio of evaluated savings to tracked savings.                                                                                                                                                                                                                                                                                           |
| <b>Sample size</b>              | The number of observations or replicates included in a statistical sample.                                                                                                                                                                                                                                                                   |
| <b>Secondary market impacts</b> | Energy consumption of appliances that would have been transferred to the secondary market if said appliances had not been retired.                                                                                                                                                                                                           |
| <b>Spillover</b>                | Savings attributable to participants who implement the energy efficiency measure(s) introduced by a program after participating in it once, without participating in the program a second time.                                                                                                                                              |
| <b>Tracked savings</b>          | Gross and net savings calculated based on various parameters such as number of participants or units installed or sold, unitary savings values, installation rates, interactive effects, and net-to-gross ratios. Those parameters, except the number of participants or units installed or sold, are obtained from the previous evaluation. |
| <b>Unitary savings</b>          | Energy or peak demand savings established on a unitary basis. A unit can either be a product (e.g. an 8 W LED lamp), a capacity (e.g. one-tonne capacity of an air-source heat pump), or a participant (e.g. one participant taking part in a behaviour-based program).                                                                      |

## EXECUTIVE SUMMARY

This report presents the 2024 demand-side management (DSM) results of the Efficient Product Rebates program administered by EfficiencyOne (E1). This program is comprised of the Business Energy Rebates (BER) program component. Through its Application Rebates (BER-AR) and Instant Rebates (BER-IR) services, BER provides financial incentives in the form of prescriptive rebates or financing to business, non-profit, and institutional (BNI) participants to encourage reductions in electricity consumption and demand.

### Evaluation Approach

The 2024 evaluation was aimed at calculating program component gross and net results, namely electrical first-year and lifetime energy savings, peak demand savings, as well as avoided greenhouse gas (GHG) emissions. Table 1 summarizes the types of evaluation conducted for the program component and the corresponding methodology.

**Table 1: Summary of 2024 Efficient Product Rebates Program Evaluation**

| Program Component | Evaluation Type                                                        |         |        | Methodology                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| * The average NTGR values presented in the total correspond to the ratios of net savings to gross savings for both Application Rebates and Instant Rebates. |                     |               |               |                  |        |             |                  |

Efficient Product Rebates was aimed at achieving 39.747 GWh in net electrical energy savings and 5.107 MW in net peak demand savings at the generator for 2024. The program nearly reached the planned net electrical energy savings, falling short by less than 1%, and exceeded the peak demand savings target by 13%. Instant Rebates was the largest contributor to total program net energy and peak demand savings.

The following subsections present evaluation results at the program component level.

## BER Findings and Recommendations

This subsection presents the key findings and recommendations from the 2024 BER evaluation.

**2024 BER-Finding:** BER net electrical energy savings almost reached the target of 39.747 GWh, falling short by less than 1%, and exceeded the planned net peak demand savings of 5.107 MW by 13%.

**2024 BER-Finding:** In 2024, Instant Rebates participation decreased by 26% with fewer measures rebated. In 2024, Application Rebates participation increased with 18% more participating businesses and with net savings per participant also increasing by 16% compared to 2023. Overall, BER gross electrical energy savings and peak demand savings decreased by 2% and 9% respectively compared to 2023 levels. This was mainly due to the decrease in Instant Rebates savings generated by LED linear lamps and LED linear fixtures.

**2024 BER-Finding:** Overall satisfaction with Instant Rebates is high among both participants and distributors with reported average satisfaction ratings of 9.1 and 8.3 out of 10 respectively.

**2024 BER-Finding:** The Instant Rebates free-ridership algorithm was updated in 2024 and the overall free-ridership levels established in the 2024 evaluation ranged between 8% and 15%, which represent a decrease from the 2022 evaluation.

**2024 BER-Finding:** Both evaluated net electrical energy savings and peak demand savings were identical to the values tracked by E1 for Application Rebates. Evaluated net electrical energy and peak demand savings were both 4% and 6% higher respectively than tracked results for Instant Rebates.

**2024 BER-Finding:** The fixture market has transitioned to LED, with non-LED options now rare. They report 100% LED stock for linear and high-bay fixtures and 99% for outdoor fixtures. Manufacturers no longer supply non-LED alternatives, and this market share is expected to remain stable without E1 incentives.

**2024 BER-Finding:** Most purchases rebated through BER-IR are for new construction or products at the end of their useful life, which validates the use of a replace-on-burnout baseline for this program component.

**2024 BER-Finding:** The market evaluation results indicate that the market practice for BNI fixtures is LED technology, indicating that an update to the baseline for fixtures sold through BER-IR is imminent.

**Recommendation #1:** Undertake additional research to further validate the market evaluation results to establish, no later than Q3, when the LED baseline for BER-IR LED fixtures should take effect. Research should focus on the potential risk of the fixture market rebounding from reducing or removing the Instant incentives in the Nova Scotia market.

**2024 BER-Finding:** The LED market practice baseline for BNI fixtures also applies to new construction projects incented through BER-AR.

**Recommendation #2:** Review the eligibility criteria for LED lighting in new construction projects in BER-AR given evidence that LEDs are the baseline for this market.

**2024 BER-Finding:** Distributors reported that most of their fixture stock is DLC Premium or DLC Standard, with a small portion being non-certified. They expect the market to remain certified even without E1 incentives, though this should be monitored.

**Recommendation #3:** In line with Recommendation #1, research should also investigate the efficiency level of an LED baseline for LED fixtures.

**2024 BER-Finding:** Distributors still carry a small percentage of non-LED lamps for a subset of customers. They forecast this share to diminish even more over the next two years as more fixtures are replaced with LEDs.

**Recommendation #4:** The current non-LED baseline for lamps should be maintained for BER-IR and reassessed in 2026. Given trends, E1 should plan for a baseline change starting in 2027.

**2024 BER-Finding:** Lighting retrofit opportunities remain for early replacements and particularly in some subsectors where capital funding is limited, like institutional and government buildings and to a lesser extent property management companies.

**Recommendation #5:** Plan for a shift in the product offer for LED fixtures from BER-IR to BER-AR to capture remaining retrofit opportunities once LED baseline is adopted for BER-IR.

**Recommendation #6:** Focus efforts on BER-AR to target market laggards for early replacement retrofits of their lighting.

**Recommendation #7:** A LED baseline should also be applied to the EUL of LED fixtures rebated through BER-AR and SBES to reflect the fact that existing fixtures would have been replaced with LED fixtures at the end of their life. The baseline should consider the proportion of projects targeted for early replacement versus replace on burn-out as well as an estimated remaining EUL.

**2024 BER-Finding:** Distributors report that control products continue to evolve.

**Recommendation #8:** Analyze opportunities for increasing interest around controlled lighting products.

**2024 BER-Finding:** There is an increase in multi-wattage and multi-voltage fixture products available on the market.

For these products, the tracked wattage may not necessarily be the wattage used for all applications.

**Recommendation #9:** Ensure that multi-wattage products are identified in the tracking sheet. Update applications for BER-AR and SBES to identify multi-wattage products and confirm the wattage being used. Select the middle wattage (i.e. not the lowest or highest) as the tracked wattage when information is not available from the participant.

## Program Tracked and Evaluated Savings

Table 3 below compares E1 tracked electrical energy and peak demand savings to evaluated savings at the generator. It also includes the realization rate, representing the ratio of evaluated net savings to tracked net savings, for both electrical energy savings and peak demand savings. Furthermore, the NTGRs are also presented and correspond to the rounded averages obtained by dividing net savings by gross savings, which explains why the NTGR values are different from those presented in the other sections.

**Table 3: Comparison of 2024 Tracked and Evaluated Savings at the Generator**

|                                                                                                                                                                                                            |                       | Gross Savings |      | NTGR* | Net Savings |      | Realization Rate |

| BER                                                                                                                                                                                                        | Energy Savings        |               |      |       |             |      |                  |
|                                                                                                                                                                                                            | Tracked Savings by E1 | 47.777        | GWh  | 0.81  | 38.557      | GWh  | 103%             |
|                                                                                                                                                                                                            | Evaluation Results    | 46.852        | GWh  | 0.84  | 39.529      | GWh  |                  |
|                                                                                                                                                                                                            | Peak Demand Savings   |               |      |       |             |      |                  |
|                                                                                                                                                                                                            | Tracked Savings by E1 | 6.752         | MW   | 0.81  | 5.479       | MW   | 105%             |
|                                                                                                                                                                                                            | Evaluation Results    | 6.756         | MW   | 0.85  | 5.746       | MW   |                  |
| *Different NTGRs were established for Application Rebates and Instant Rebates. The average NTGR values presented in this table correspond to the ratios of net savings to gross savings for both services. |                       |               |      |       |             |      |                  |

Evaluated net electrical energy and peak demand savings established through this evaluation were both 3% and 5% respectively higher than those calculated in the 2024 tracking sheet. The differences are attributed to updates to the unitary savings values and NTGRs for Instant Rebates.

## INTRODUCTION

EfficiencyOne (E1), an independent, non-profit organization, is responsible for helping Nova Scotians improve the energy efficiency of their homes and workplaces by designing, marketing, and delivering demand-side management (DSM) for Nova Scotians. E1 provides energy efficiency, demand response and carbon mitigation services through the Efficiency Nova Scotia (ENS) franchise. Regulatory oversight of its DSM activities is provided by the Nova Scotia Utility and Review Board (NSUARB). E1 receives funding for its electricity DSM activities from Nova Scotia Power (NS Power) ratepayers.

E1 has a DSM portfolio of three residential programs, three business, non-profit, and institutional (BNI) programs, and one demand response (DR) program that are marketed to Nova Scotians through the ENS franchise. Each program has one or more program components. Econoler was commissioned by E1 to evaluate E1's 2024 DSM program portfolio

This evaluation report relates to the Efficient Product Rebates program that is comprised of Business Energy Rebates (BER) program component. Table 4 below lists the Efficient Product Rebates program component and the type of evaluations conducted for 2024. A comprehensive impact evaluation involves reviewing the following four key elements: (1) the baseline definition; (2) the savings calculation methodology; (3) the values of the parameters used to calculate savings; and (4) NTGRs. A condensed impact evaluation involves using some or all of the previous year's impact evaluation parameters such as unitary savings values, adjustment ratios, installation rates, and net-to-gross ratios (NTGRs) to provide evaluated results.

**Table 4: Types of Evaluations Conducted for Each Program Component, 2024**

| Program                   | Program Component | 2023    |        |                                      |
|---------------------------|-------------------|---------|--------|--------------------------------------|
|                           |                   | Process | Market | Impact                               |
| Efficient Product Rebates | BER               | X       | X      | Comprehensive (IR)<br>Condensed (AR) |

For each program, the Evaluator prepared a DSM evaluation report presenting key findings, electrical first-year and lifetime energy savings, peak demand savings, and avoided greenhouse gas (GHG) emissions.<sup>1</sup>

<sup>1</sup> Unless specified otherwise, electrical energy savings refer to first-year energy savings rather than lifetime energy savings throughout this report.

# 1 BER Overview

This section describes Business Energy Rebates (BER) program component, follows up on past evaluation recommendations, and presents participation history.

## 1.1 BER Description

BER provides financial incentives in the form of prescriptive rebates or financing to business, non-profit, and institutional (BNI) participants to foster reductions in electricity consumption and peak demand. All businesses, non-profits, and institutions in Nova Scotia are eligible. Figure 1 presents an overview of the program component.

Figure 1: BER Overview

The term prescriptive rebate refers to a particular rebate value that is calculated prior to a participant purchasing an eligible measure. If a given measure or technology demonstrates energy savings potential, a corresponding rebate value is applied to the purchase price of the measure or technology.

Measures offered through BER must meet specific criteria including minimum efficiency/efficacy values as well as industry standards such as ENERGY STAR® certified performance levels or those established by the DesignLights Consortium (DLC) and the National Electrical Manufacturers Association.

Rebates offered through BER are delivered through two services, the Application Rebates (AR) service and the Instant Rebates (IR) service. Instant Rebates reaches a greater number of participants and offers quick and convenient access to BER but is limited in tracking participant details. Conversely, Application Rebates allows for better project-level control since more participant details are provided to E1. All BER technologies are available through Application Rebates, while only certain lighting and pumping technologies are eligible through Instant Rebates.

Instant Rebates is delivered through a network of participating distributors in the Province of Nova Scotia. These distributors play a key role in promoting Instant Rebates to end users. Distributors also provide customer services for measures that are only eligible through Application Rebates by sharing their expertise and assisting with completing applications. Two new participating distributors were added in 2024, bringing the total to 17.

In an effort to increase participation, E1 increased rebate amounts and caps on select lighting measures for four lighting categories in May 2024 in both Application Rebates and Instant Rebates.

BER was aimed at achieving 39.747 GWh in net electrical energy savings and 5.107 MW in net peak demand savings at the generator in 2024.

## **1.2 Follow-up on Past Evaluation Report Recommendations**

No recommendations were made for BER in 2023.

## **1.3 Participation History**

### **BER Application Rebates**

In 2024, 15,644 units were rebated through 262 projects that were implemented by 199 unique participants<sup>2</sup> under Application Rebates. Figure 2 below illustrates how Application Rebates participation has evolved since 2015. The number of participating businesses increased in 2024 with 18% more participating businesses compared to 2023. This increase in participants correlated to a 15% increase in the number of completed Application Rebates projects. Finally, the gross electrical energy savings achieved per participant increased by 16%.

---

<sup>2</sup> The number of unique participants in Application Rebates corresponds to the number of businesses that participated in the service.

**Figure 2: Overview of Participation in Application Rebates, 2016-2024**

Figure 3 below illustrates the distribution of gross electrical energy savings among Application Rebates measure categories. The lighting and motor measure categories accounted for most Application Rebates savings (82% in total). The motors category saw the greatest increase in savings, generating 27% of total program savings compared to less than 10% in 2023. This was largely due to one large project that generated 2.998 GWh in electrical energy savings. The commercial kitchen, refrigeration, and pumping measure categories each accounted for less than 1% of total savings. The IT and data centre, water heating, pool, compressed air, and laundry measure categories are not included in Figure 3 since no projects in those measure categories were submitted in 2024.

**Figure 3: Distribution of 2024 Application Rebates Gross Electrical Energy Savings by Measure Category**

## BER Instant Rebates

While participant information tracking has improved in the past few years and the tracking sheet indicates the total number of measures rebated through the service, the available data collected by distributors do not allow determining the number of unique Instant Rebates participants, leading to the participation metric being the number of measures rebated. As outline in Figure 4 below, 177,358 measures were rebated through Instant Rebates in 2024, a 26% decrease compared to 2023 levels.

**Figure 4: Instant Rebates Measures Rebated, 2015-2024**

As outlined in Figure 5 below, participation levels decreased for the three main lighting measures in 2024, with LED linear lamps having the largest decrease of 41% compared to 2023. While LED linear fixtures also decreased by 10%, levels for all other measures, i.e. occupancy/motion sensors, circulator pumps, and LED directional and architectural fixtures, each increased by slightly less than 30%.

**Figure 5: Instant Rebates Measures Rebated, 2023-2024**

Figure 6 below provides an overview of the distribution of Instant Rebates gross electrical energy savings among pumping and lighting measures. In 2024, LED linear fixtures generated the largest share of gross savings (56%) followed by LED outdoor fixtures (27%) and LED linear lamps (13%).

**Figure 6: Distribution of 2024 Instant Rebates Gross Savings by Measure**

## BER Overall

As presented in Figure 7 below, BER generated a total of 46.852 GWh in gross electrical energy savings at generator in 2024, which represents a 2% decrease compared to 2023 results. In 2024, gross peak demand savings totalled 6.756 MW for Application Rebates and Instant Rebates, representing a 9% decrease from 2023. This was mainly due to the decrease in Instant Rebates savings generated by LED linear lamps and LED linear fixtures.

**Figure 7: Evolution of BER Gross Savings, 2015-2024**

## 2 BER Evaluation Approach

The 2024 BER-AR evaluation included a condensed impact evaluation, while the BER-IR evaluation included a comprehensive impact evaluation as well as a process evaluation and market evaluation. The main objectives of the 2024 BER evaluation were as follows:

- › Collect information on participant and distributor perspectives
- › Calculate gross and net BER results (for both AR and IR), namely first-year and lifetime electrical energy savings, peak demand savings, as well as avoided GHG emissions
- › Analyze the evolution of the BNI lighting market

The Evaluator identified key research questions aimed at achieving these objectives. Table 5 below outlines the evaluation objectives and maps them to the Evaluator's research questions, methods, and sample sizes (n). Each method is described further below.

**Table 5: 2024 BER Evaluation Approach**

| Evaluation Objectives                                           | Research Questions                                                                                                                                                                                                                                                                                                                                                                         | Methodology                                                                                                                                                                                                                                                                                                                                                                        |

<sup>3</sup> The 2024-2025 DSM MA is a reference document that provides an in-depth review of all necessary parameters to calculate the annual and lifetime gross energy and peak demand savings of most prescriptive measures and some semi-prescriptive measures offered through E1's DSM program portfolio. In addition, the Measure Assessment includes effective useful life values for all measures offered in E1's program portfolio. For the evaluations conducted during the last two years of the 2023-2025 DSM cycle, the Evaluator refers to the values presented in the 2024-2025 DSM MA.

| Evaluation Objectives                            | Research Questions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Methodology                                                                                                                                                       |

## Instant Rebates Participant Survey

In November 2024, Narrative Research conducted a telephone survey with a total of 50 Instant Rebates participants. The average length of the survey was 14 minutes. The questionnaire is presented in Appendix I, and complete survey results are outlined in Appendix II. Since it is not possible to obtain a complete list of Instant Rebates participants due to the nature of this service, the margin of error is calculated using a conservative assumption that the service population is infinite. Drawing a random sample of 50 from an infinite population yields a margin of error of 11.8% at a 90% confidence level. Although the margin of error is higher than the  $\pm 10\%$  target, the Evaluator finds it acceptable for the purpose of this evaluation.

## Instant Rebates Interviews with Distributors

In November 2024, Narrative Research conducted ten interviews with Instant Rebates participating distributors. Interviews lasted between 35 and 65 minutes, with an average length of 47 minutes. Participants were recruited from a list of distributors provided by E1 and were given an incentive of \$100 to participate. Interviews took place over the phone between October 23 and November 25, 2024. The aim of the interviews was to collect information on distributor perspectives regarding the service and market evolution. The list of distributors was provided by E1, and the Evaluator confirmed the decision-maker by verifying that the person interviewed was the most knowledgeable about stocking and supplying specific products eligible for rebates under the service. The methodology used to identify the decision-maker was consistent with previous market evaluations. The guide used for the interviews is presented in Appendix III.

## Tracking Sheet Audit

Prior to performing the savings calculation review, the Evaluator performed an audit of the final 2024 tracking sheets to ensure they were complete and the entered data were consistent. The detailed protocols used for the Application Rebates and Instant Rebates tracking sheet audits and the results obtained are presented in Appendix IV and Appendix V respectively.

## Unitary Savings Review

As part of the 2024-2025 DSM MA activities and based on the results of both a literature review and a tracking sheet data review, the Evaluator reviewed the equations, parameters, and assumptions used to establish savings values for ten BER measures and established unitary savings values for the new variable frequency drive (VFD) for non-HVAC (Heating, Ventilation, and Air Conditioning) applications measures offered under Application Rebates. The 2024-2025 DSM MA was then updated accordingly.

## Effective Useful Life Update

As part of the 2024-2025 DSM MA update activities, the Evaluator also reviewed the effective useful life (EUL) values for all measure categories and recalculated the EUL values of lighting measures for which baseline changes are anticipated during the measure lifetimes.

## Calculations Using Evaluation Results

Building on all the above methods and collected data, the Evaluator calculated first-year and lifetime energy savings as well as peak demand savings as per the calculation methodologies presented in Section 4 and Section 5 below.

## GHG Emission Reduction Calculations

To obtain net avoided GHG emissions in CO<sub>2</sub> eq for BER, the Evaluator multiplied the net energy savings by the latest Nova Scotia-specific factor for GHG emissions generated by electricity production. This factor was established using NS Power data.

### Note on Margin of Error

For evaluation activities that yield quantitative results based on a sample, the Evaluator aimed to achieve a maximum margin of error of 10% at a confidence level of 90%. This means that, if measurements were conducted many times with different samples, the data would be within 10 percentage points above or below the percentage reported 90% of the time. Thus, the margin of error indicates the relative level of precision<sup>4</sup> of a measurement, while its associated confidence level indicates the probability of a measurement falling within the margin of error.<sup>5</sup>

As part of the condensed BER-AR evaluation, no data-collection activities warranted the calculation of margins of error.

For BER-IR, the Evaluator calculated the margins of error for free-ridership levels. The margins of error are listed alongside results in the applicable sections below. Examples of calculations used to establish margins of error are provided in Appendix II of the 2024 DSM Programs Evaluation Executive Summary.

## Market Characterization Study

The Evaluator completed a market evaluation in 2024 to assess the state of the lighting market and review whether any baselines for BNI lighting products should be recommended for update. The analysis and recommendations from the market evaluation account for the different approaches in the programs targeting BNI lighting. BER-IR uses a standard practice baseline given the rebate is provided at the time of sale. Therefore, the stocking practices of distributors and availability of LED versus non-LED technologies have a direct link to the BER-IR baseline. By contrast, for BER-AR and SBES, which are primarily retrofit programs, the baseline is calculated as the difference between the existing technology performance and the performance of the measure and assumes early replacement. For BER-AR and SBES retrofit projects, the stocking practices of distributors also have an impact on measure lifetimes.

---

<sup>4</sup> Precision refers to how reproducible a set of measurements is. However, it does not consider how close the measured values are to the true values; this would refer to accuracy.

<sup>5</sup> As part of this evaluation, the confidence levels and margins of error only take random sampling errors into account; they do not reflect non-sampling errors or biases such as data entry errors, inaccurate responses from respondents, or the inability to contact certain people.

## 3 Process Evaluation for Instant Rebates

This section summarizes the findings obtained during the Instant Rebates participant survey and interviews conducted with Instant Rebates distributors.

### 3.1 Participant Awareness and Decision to Purchase

#### Instant Rebates Participants

Of all IR survey participants (n=50), six in 10 said they purchased energy efficient products (that were available for IR) for their own organization (60%), while nearly four in 10 (38%) either said they purchased the products for a customer/project outside of their organization or that they are contractors.

Most contractors (89%) said that they or someone else in their organization usually makes the decision to buy efficient products rather than standard products. One in 20 (5%) indicated that both they and the customer make the decision together, and the same proportion (5%) said it is someone else who makes the decision.

Among participants who purchased efficient products for their organization and those who said it is either they or someone else in their organization who makes the decision to purchase efficient products (n=47), one-third (32%) said the main activity of their organization is electrical contracting/installation. This was followed by one in eight saying the main activity of their organization is residential (13%), and one in ten (11%) identifying the main activity as manufacturing/industrial. Among these same participants, 81% stated that they had not considered any other alternative LED lighting products to the efficient products they purchased. Among those who did consider alternative products (n=7), two participants said they considered standard LED lighting, and one participant said they considered fluorescent lighting. Those who considered alternatives to linear or outdoor fixtures (n=6) cited standard/incandescent halogen bulbs, LED tubes, and low-pressure sodium lamps as options.

About four in ten participants (43%) said energy efficiency was the single most important reason they purchased efficient products over standard products. This was followed by one in eight (13%) doing so for cost savings. One in 10 cited either the availability of other alternatives (11%), ENS program incentives (9%) or the lifespan of efficient products (9%). When asked for the second most important reason, one in four (26%) cited energy efficiency, one in five (19%) said cost savings, and one in eight said either better lighting (13%) or the lifespan of efficient products (13%). One in 10 (9%) said updating their equipment was the second most important reason, with a few citing a range of other factors.

Half (52%) of surveyed participants said their distributor recommended the efficient product to them, while four in 10 (40%) said their distributor did not.

For 74% of surveyed participants, distributors are the primary source of awareness about rebates available from BER. Online sources were second (9%), while word of mouth, past experience with another ENS program, and contractors were each mentioned by 4% of participants.

## 3.2 Participant Satisfaction

### Instant Rebates Participants

Participants were asked about their level of satisfaction with different service elements on a ten-point scale where 1 means “Not at all satisfied” and a 10 means “Completely satisfied”. Overall, Instant Rebates received an average satisfaction score of **9.1**, which indicates that the vast majority of participants (94%) are highly satisfied with the service. Considering the interaction and communication they had with distributors, eight in 10 participants (82%) said they were highly satisfied (scores from 8 to 10), while fewer than one in 10 (8%) said they were moderately satisfied (scores from 5 to 7) and only one in 50 (2%) said they were unsatisfied (scores from 1 to 4). Similarly, eight in 10 participants (82%) said they were highly satisfied with rebate amounts, one in 10 (12%) was moderately satisfied, and none (0%) was unsatisfied. The satisfaction score for Instant Rebates eligible products, although the lowest among the service elements, remains relatively strong with 68% of participants saying they were highly satisfied, 20% saying they were moderately satisfied, and just 4% saying they were dissatisfied.

Among those who were unsatisfied with the interaction and communication they had with distributors (n=5), two attributed their score to a lack of communication with and availability of distributors, and one cited slow communication and having distributors that were less knowledgeable about Instant Rebates. Among the few (n=6) only moderately satisfied with the rebate amounts, most (five) said the rebates were too low or they expected higher rebate amounts. One cited the absence of rebates on some products as a reason for their dissatisfaction.

**Figure 8: 2024 Participant Satisfaction with Instant Rebates (10-point Scale)**

Note: Mean score of ratings on a scale of 1 to 10, where 1 means “Not at all satisfied” and 10 means “Completely satisfied”. Excludes “Don’t know” responses.

The majority of participants (66%) had no suggestions for improving Instant Rebates. However, suggestions included increasing rebates (10%), more instant rebates (preferred over mail-in, 8%), simplifying the paperwork (8%), making more measures eligible for rebate (6%), and/or better marketing/awareness (6%).

### 3.3 Distributor Satisfaction with Instant Rebates

Distributors (n=10) were asked to express their level of satisfaction with various aspects of Instant Rebates using a 10-point scale where 1 means “Not at all satisfied” and 10 means “Very satisfied”.

Satisfaction with the service overall is high, with an average score of 8.3 out of 10. Seven distributors rated their satisfaction between 8 and 10, while all three others provided a score ranging from 5 to 7. For the three distributors with lower satisfaction, their dissatisfaction with Instant Rebates primarily stems from questioning the benefits of the service given the maturity of LED lighting technology and the reduced availability of non-LED as alternative products (see Section 7 below).

Satisfaction with the service support and communications provided by E1 is very high with an average score of 9.3 out of 10. All distributors provided a satisfaction rating between 8 and 10.

In general, distributors were also pleased with rebate processing, tracking, and reporting, with an average satisfaction score of 8.4 out of 10. Seven distributors rated a high score of 9 or 10, while the others provided scores of 4, 6, and 7. Dissatisfaction stems from the time-intensive administration requirements, including having to manually review sale entries for accuracy. Table 6 presents the average satisfaction ratings provided by distributors for each assessed aspect.

**Table 6: 2024 Distributor Satisfaction with Instant Rebates (10-point Scale)**

|                                                   | Distributors |             |
|---------------------------------------------------|--------------|-------------|
|                                                   | Mean*        | Sample Size |
| Overall Service                                   | 8.3          | 10          |
| Service Support and Communications provided by E1 | 9.3          | 10          |
| Rebate Processing, Tracking, and Reporting        | 8.4          | 10          |

\* Scale: 1 = Not at all satisfied; 10 = Very satisfied

### 3.4 Service Influence on Distributors

Similar to 2022, distributors of LED linear fixtures, LED linear lamps, and LED outdoor fixtures were questioned about the different strategies employed to sell each of these product categories in 2024. The promotion of Instant Rebates was a key sales tactic across lighting categories. In addition, a good number of distributors actively encouraged customers to purchase LED products and promoted those products in their marketing. These strategies were far more common for LED fixtures than for LED lamps. Many also reduced the price of qualifying LED products either through a discount or bundled pricing. While distributors increased their stock and assortment of LED fixtures in 2024 to support sales, this was not a strategy used for LED linear lamps. Finally, four distributors conducted training workshops on LED outdoor fixtures for their contractor customers.

It should be noted that distributor’s sales strategies were implemented in the context of very limited non-LED alternatives and therefore caution should be used in interpreting results (for further details see Section 7). When asked about whether they actively encouraged or promoted customers to purchase LED fixtures instead of less efficient products, several distributors noted unaided that while they promote LED products, they don’t stock non-LED alternatives “...we have promoted the products but not over less efficient technologies...”.

The main reported strategies are highlighted in Table 7.

**Table 7: 2024 Distributor Sales Strategies Used for Qualifying LED Products**

| Distributor Sales Strategies                                                                                              | Number of Distributors Using the Strategy (n=10) |                  |                      |
|---------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------|------------------|----------------------|
|                                                                                                                           | LED Linear Fixtures                              | LED Linear Lamps | LED Outdoor Fixtures |
| Promote the E1 rebate in any way                                                                                          | 10                                               | 8                | 10                   |
| Encourage customers to purchase LED products instead of less efficient products/upsell customers to purchase LED products | 10                                               | 6                | 9                    |
| Promote LED products over less efficient products in your marketing/<br>promote LED products in your marketing            | 7                                                | 6                | 9                    |
| Reduce the price of qualifying LED products                                                                               | 7                                                | 5                | 6                    |
| Increase the stock or assortment of LED products                                                                          | N/A                                              | 1                | 8                    |
| Increase the variety of LED products                                                                                      | 6                                                | N/A              | N/A                  |
| Increase the stock of LED products                                                                                        | 7                                                | N/A              | N/A                  |
| Conduct training workshops on LED products for contractor customers                                                       | N/A                                              | 0                | 4                    |

Other sales strategies used in 2024 for LED linear fixtures included bundled pricing by manufacturers, purchase raffles, increased sales outreach to customers, sales bonuses or raffles for staff, and store displays. Specific strategies used to sell LED outdoor fixtures included store displays, bundled discounts, and in-store raffles for customers. Distributors did not invest additional efforts on selling LED linear lamps in 2024 due to increased customer interest in fixtures over lamps. Only one distributor mentioned having had a store display to increase their sales of LED linear lamps. Of note, one distributor mentioned looking at incorporating lighting recommendations when conducting energy audits for their customers to increase their sales of LED lighting products.

Distributors' desire for increased sales and profits had the greatest influence on their sales strategy choices for qualifying LED products, closely followed by product quality or value. The incentives offered by E1 were also an important influence in each lighting category, although it was the most important for LED Outdoor Fixtures, where more distributors rated this factor as "Very influential". The distributors' policies and desire to support sustainability closely follows. The influence of ENS's educational, promotional, and marketing efforts and support was minimal in determining how to increase the sales of qualifying LED lighting products in 2024. A summary of ratings is provided in Table 8.

**Table 8: 2024 Influences on Distributors' Sales Strategies**

|                                                                                      | Very/Somewhat Influential (n=10) |                  |                      |
|--------------------------------------------------------------------------------------|----------------------------------|------------------|----------------------|
|                                                                                      | LED Linear Fixtures              | LED Linear Lamps | LED Outdoor Fixtures |
| Your company's interest in increasing your sales and profits                         | 10                               | 10               | 9                    |
| Quality or value of LED products                                                     | 10                               | 7                | 10                   |
| Incentives offered by E1                                                             | 8                                | 8                | 9                    |
| Your company's policies and desire to support sustainability                         | 8                                | 7                | 9                    |
| Educational, promotional and marketing efforts and support provided or driven by ENS | 4                                | 2                | 4                    |

A small majority of distributors reported that they would have used the same sales approach for LED fixtures in the absence of the program. Conversely, a similar majority reported that for linear lamps their sales strategy would have likely differed in the absence of the program.

### 3.5 Distributor Successes and Challenges with Instant Rebates

While distributors were not asked specifically about strengths and successes associated with Instant Rebates, two distributors mentioned that they appreciate program staff attention, responsiveness to feedback, engagement with distributors, and communications, and they would like to see this continued.

Four distributors experienced challenges related to Instant Rebates in 2024, although there were no consistencies in the types of issues reported. Challenges with the service (each mentioned by one distributor) included the administrative burden and additional staffing costs associated with the tracking and reporting functions, a difficult onboarding process with unclear instructions and limited assistance from E1 in guiding new service delivery partners, losing sales to retailers participating in Instant Savings, and disqualifying customers who run their small business out of their homes from participating in Instant Rebates.

Very few suggestions were provided for service improvement. Three distributors questioned the service's relevance given the widespread adoption of many LED products. As such, they would like to see Instant Rebates explore new ways to incentivize energy efficiency, including offering rebates on electric vehicle (EV) chargers and smart lighting technologies (e.g. dimmers). Other recommendations on Instant Rebates included increasing social media advertising as well as moving to a mail-in rebate offering to reduce the administrative burden on distributors and gain greater control over who receives the rebates (i.e. ensuring end users benefit from the rebate rather than contractors).

#### 2024 BER Participant and Distributor Perspective Highlights

- › The majority of Instant Rebate survey participants purchased energy efficient products for their own organization, while fewer purchased the products for a customer/project outside of their organization or are contractors.
- › The primary factors influencing Instant Rebate participants to purchase energy efficient products were to improve energy efficiency and help with cost savings.
- › Participant satisfaction with the Instant Rebate service is very high, with an overall satisfaction rating of 9.1.
- › Participant satisfaction with the interaction and communication with distributors as well as the rebate amounts is also very high (both receiving average ratings of 9.0).
- › Increasing rebates, improving the number of instant rebates (instead of switching to a mail-in offering), and simplifying the paperwork are the most cited participant suggestions to improve the Instant Rebate service.
- › Distributors deployed several sales strategies to promote LED products and were influenced by Instant Rebates in their decision to do so. The two most used strategies were promoting the E1 rebate and encouraging customers to purchase LED products instead of less efficient products.
- › Distributors reported high levels of satisfaction with Instant Rebates overall, the support and communications provided by E1, and rebate processing, tracking, and reporting, with average ratings of 8.3, 9.3, and 8.4 respectively on a 10-point scale. The main points of dissatisfaction for a few of the distributors were the burden and costs of administering the service and the perception that incentivizing certain LED lighting products no longer contributes to product adoption.
- › Distributor suggestions to improve Instant Rebates included expanding eligibility to other energy saving technologies (e.g. EV chargers, dimmers), increasing social media advertising, and switching to a mail-in rebate offering.

## 4 Impact Evaluation for Application Rebates

The objectives of the 2024 Application Rebates impact evaluation were to determine gross and net electrical energy and peak demand savings.

### 4.1 Tracking Sheet Audit

To ensure service results were reliably compiled, the Evaluator first performed a tracking sheet audit aimed at verifying the completeness and consistency of the data submitted by E1. The results obtained from the tracking sheet audit are presented in Appendix IV. The tracked savings results presented in this report therefore refer to the corrected tracked savings obtained by the Evaluator.

### 4.2 Gross Savings

Gross savings refer to changes in energy consumption resulting from actions taken by participants regardless of their reasons for participating.<sup>6</sup> For each Application Rebates project, E1 tracks annual gross savings using the equations defined in the most up-to-date BER CIRx Screening Tool (version 1.6), an E1 tool presenting the savings calculation methodologies, assumptions, and equipment parameters specific to each project.

#### 4.2.1 Adjustment Ratios

The Evaluator applied adjustment ratios to the tracked gross savings to determine evaluated gross savings. These ratios were established using 2022 project review results, with the exception of the lighting measure category for which the ratio was not updated in 2022; instead, values established in the 2021 evaluation were applied. All those ratios are documented in the 2024-2025 DSM MA.

As part of the 2023 Custom Retrofit evaluation, the Evaluator developed adjustment ratios to be applied to solar PV projects. These adjustment ratios are based on observed discrepancies between modelled savings and measured savings and are meant to be applied to modelled electrical energy savings estimates as part of the initial energy savings calculations separate from the standard adjustment ratios based on project review findings. For projects modelled in RETScreen Expert, the adjustment ratio is 0.942. For projects modelled in PVWatts, the adjustment ratio is 1.101. These solar PV adjustment ratios were not applied by E1 in 2024. Moving forward, E1 is encouraged to apply these adjustment ratios to solar PV projects to more accurately represent savings.

#### 4.2.2 Interactive Effects

Interactive effects occur when the implementation of energy efficiency measures has an impact on the energy consumption of other elements such as heating and cooling; these are considered in the gross savings standard equation presented in the BER CIRx Screening Tool. For BER, interactive effects only apply to indoor lighting projects. The interactive effects factors for the commercial sector are based on the same interactive effects as in previous years, as detailed in the 2024-2025 DSM MA. Based on site visit observations during a previous evaluation, the Evaluator ensured that E1 used the correct interactive effects factors for visited projects. When applicable, the Evaluator adjusted the interactive effects factor based on the BER CIRx Screening Tool value that most accurately corresponded to site observations. Lighting interactive effects adjustments are included in the adjustment ratio applied in the 2024 evaluation and are presented in Subsection 4.2.1 above.

---

<sup>6</sup> Definition adapted from National Renewable Energy Laboratory, The Uniform Methods Project Chapter 23: Estimating Net Savings: Common Practices, September 2014, p. 3.

### 4.2.3 Effective Useful Life

As part of the 2024-2025 DSM MA activities, the Evaluator reviewed the EUL values used in the calculations of electrical energy savings that are expected to persist over time. In 2024, for LED linear fixtures, LED linear lamps, LED outdoor fixtures, and LED directional and architectural fixtures, EUL values were slightly adjusted as a result of hours of use (HOU) value updates. For all other Application Rebates measures, the EUL values established in the 2021 evaluation remained valid for the 2024 evaluation.

The tracked and evaluated EUL values are presented in Table 9.

**Table 9: Updated BER AR EUL Values**

| Measure                                                              | Tracked EUL | Evaluated EUL |
|----------------------------------------------------------------------|-------------|---------------|
| <b>LED Linear Fixtures</b>                                           |             |               |
| 1 x 4 Luminaires                                                     | 11.6        | 11.9          |

The evaluated equivalent EUL values are applied to each measure gross and net first-year electrical energy savings to obtain gross and net lifetime electrical energy savings. As a result, the weighted average EUL value for gross and net savings is equal to 18.9 years (see Subsections 4.2.4 and 4.3.4 below).

## 4.2.4 Evaluated Gross Savings

The savings achieved for each Application Rebates measure category are presented in Table 10 below. Both energy and peak demand savings were revised by applying the adjustment ratios discussed in Subsection 4.2.1 above.

The savings at the generator were calculated using a line loss factor that accounts for electricity losses occurring between the generator and the meter. This value is a weighted average of the line loss factors provided by NS Power for each rate code and the corresponding energy savings listed in the final 2024 tracking sheet.<sup>7</sup> The line loss factors correspond to the values submitted to the NSUARB as part of the 2014 Cost of Service Study Progress Update.<sup>8</sup>

No differences were identified between tracked and evaluated gross savings.

As presented in Table 11 below, GHG emission reductions were calculated by applying the Nova Scotia-specific factor<sup>9</sup> for GHG emissions generated by electricity production to Application Rebates gross savings.

**Table 11: Evaluated 2024 Application Rebates Gross GHG Emission Reductions**

|                                                                                             | Total         |

## 4.3 Net Savings

The Evaluator determined the net energy and peak demand savings, i.e. the electrical energy and peak demand savings that can be reliably attributed to a service, by estimating the NTGR. More precisely, the NTGR is established by considering the effects that positively or negatively affect energy savings, namely free-ridership and spillover.

<sup>9</sup> At the time of writing, 2024 data were not yet available. The Nova Scotia-specific factor was obtained from Nova Scotia Power's 2023 total system emissions data (4,931,152 CO2 eq tonnes) and total electricity generation (10,442 GWh) was drawn from the following two sources: Nova Scotia Power, Total System Emissions, <https://www.nspower.ca/clean-energy/air-emissions-reporting> (last accessed September 27, 2024), and Emera Inc., Emera Inc. 2023 Annual Report, p. 31, available at [https://s25.q4cdn.com/978989322/files/doc\\_financials/2023/ar/Emera\\_2023\\_AR\\_FINAL.pdf](https://s25.q4cdn.com/978989322/files/doc_financials/2023/ar/Emera_2023_AR_FINAL.pdf) (last accessed September 27, 2024).

### 4.3.1 Free-ridership

In the case of Application Rebates, free-ridership occurs when participants would have still implemented energy efficiency measures in the absence of the service. The free-ridership level was assessed during the 2021 evaluation using a self-report approach that involved asking participants a set of questions during a telephone survey. Since no data collection aimed at updating the free-ridership level was conducted in 2024, the Evaluator used the 2021 free-ridership level.

Table 12 outlines the free-ridership level used for the 2024 Application Rebates evaluation.

**Table 12: 2024 Application Rebates Free-ridership**

| Measure Category | Average Free-ridership Level | Margin of Error |
|------------------|------------------------------|-----------------|
| All              | 26%                          | 6.6%            |

### 4.3.2 Spillover

For Application Rebates, spillover occurs when participants implement eligible energy efficiency measures due to influence from previously participating in the service without having received any kind of additional support.

The last data collection for Application Rebates spillover was conducted in the 2021 evaluation, and found that the spillover level was zero, hence a spillover level of 0% was used for the 2024 evaluation.

### 4.3.3 Net-to-gross Ratio Calculation

The NTGR is calculated using the following equation.

$$NTGR = (1 - \% \text{ Free-ridership} + \% \text{ Spillover})$$

Using the free-ridership and spillover levels established for Application Rebates, the Evaluator calculated the NTGR value as presented in Table 13.

**Table 13: 2024 Application Rebates NTGR**

| Measure Category | Free-ridership | Spillover | NTGR |
|------------------|----------------|-----------|------|
| All              | 26%            | 0%        | 0.74 |

### 4.3.4 Evaluated Net Savings

Net savings are defined as the changes in energy use attributable specifically to Application Rebates. Net savings were estimated by applying the above NTGR to the evaluated gross savings as illustrated in the following equation.

$$\text{Net Savings} = \text{Evaluated Gross Savings} \times NTGR$$

Detailed results are presented in Table 14 below. The net energy savings resulted in 5,425 tonnes of CO<sub>2</sub> eq in net annual GHG emission reductions.

**Table 14: Evaluated 2024 Application Rebates Net Energy and Peak Demand Savings**

| Measure Category                                            | Agriculture  | Commercial Kitchen | HVAC          | Lighting       | Motors        | Pumping      |

No differences were identified between tracked and evaluated net savings.

## 4.4 Realization Rate

Table 15 below compares the electrical energy and peak demand savings established through the 2024 Application Rebates evaluation to those outlined in the 2024 tracking sheet. It also includes the realization rates, representing the ratio of evaluated net savings to tracked net savings, for both electrical energy savings and peak demand savings. Realization rates were 100% for both electrical energy and demand savings.

**Table 15: Comparison of 2024 Application Rebates Tracked and Evaluated Savings at the Generator**

|                                                                                                                                   | Gross Savings |      | NTGR | Net Savings |      | Realization Rate |
|-----------------------------------------------------------------------------------------------------------------------------------|---------------|------|------|-------------|------|------------------|
|                                                                                                                                   | Value         | Unit |      | Value       | Unit |                  |
| Energy Savings                                                                                                                    |               |      |      |             |      |                  |
| Tracked Savings by E1                                                                                                             | 15.526        | GWh  | 0.74 | 11.489      | GWh  | 100%             |
| Evaluation Results                                                                                                                | 15.526        | GWh  | 0.74 | 11.489      | GWh  |                  |
| Peak Demand Savings                                                                                                               |               |      |      |             |      |                  |
| Tracked Savings by E1                                                                                                             | 1.721         | MW   | 0.74 | 1.274       | MW   | 100%             |

## 5 Impact Evaluation for Instant Rebates

The objectives of the 2024 Instant Rebates impact evaluation were to determine gross and net electrical energy and peak demand savings.

### 5.1 Tracking Sheet Audit

To ensure program service results were reliably compiled, the Evaluator first performed a tracking sheet audit to verify the completeness and consistency of the data submitted by E1. The results obtained from the tracking sheet audit are presented in Appendix V. The tracked savings results presented in this report therefore refer to the corrected tracked savings obtained by the Evaluator.

### 5.2 Gross Savings

For Instant Rebates, gross savings refer to changes in energy consumption resulting from actions taken by participants regardless of their reasons for participating.<sup>10</sup> Since the identification of eligible measures for participants is performed at the point of sale (as opposed to on site), information on participants as well as individual project operating conditions and old equipment parameters are not fully detailed in the tracking sheet. Hence, E1 estimates savings based on a set of assumptions specific to each measure type. Energy and peak demand savings are calculated for each data entry; the equations used for lighting measures include baseline wattages, the actual wattages of efficient measures, ballast factors where applicable, interactive effects factors, peak coincidence factors (PCFs), and in-service rates (ISRs), while unitary savings values are used for occupancy and motion sensors as well as circulator pump measures.

The equations, their parameters, as well as the EUL values used in the 2024 evaluation were reviewed as part of the 2024-2025 DSM MA update.

Detailed descriptions of the savings calculations are presented in the 2024-2025 DSM Measure Assessment.

#### 5.2.1 In-service Rates

Research indicates that a percentage of measures purchased through rebate programs might be stored by customers for later use. As part of the 2024-2025 DSM Measure Assessment activities, the Evaluator maintained the ISR of 85% for LED linear lamps and the ISR of 100% for fixtures, occupancy and motion sensors, as well as circulator pumps, which were established in the 2016 evaluation based on a literature review.

#### 5.2.2 Energy Savings

As part of the 2024-2025 DSM MA update, the Evaluator reviewed the equation parameters such as the hours of use (HOU) used to determine the energy savings of measures eligible under Instant Rebates. In 2024, for LED linear fixtures, LED linear lamps, LED outdoor fixtures, and LED directional and architectural fixtures, HOU values were updated based on 2021-2023 BER-AR and SBES values. The unitary energy savings values for occupancy/motion sensors were also updated in 2024. The tracked and evaluated HOU values and unitary energy savings values are presented in Table 16 and Table 17 below respectively.

---

<sup>10</sup> Definition adapted from National Renewable Energy Laboratory, *The Uniform Methods Project, Chapter 23: Estimating Net Savings: Common Practices*, September 2014, p. 3.

**Table 16: Instant Rebates Tracked and Evaluated HOU Values**

| Measure                                                              | Tracked Annual HOU (hours/year) | Evaluated Annual HOU (hours/year) |
|----------------------------------------------------------------------|---------------------------------|-----------------------------------|
| <b>LED Linear Fixtures</b>                                           |                                 |                                   |

**Table 17: Instant Rebates Tracked and Evaluated Unitary Energy Savings Values for Occupancy/Motion Sensors**

| Parameter                         | Type of Occupancy Sensor |                                | Tracked Value [kWh/year] | Updated Value [kWh/year] |
|-----------------------------------|--------------------------|--------------------------------|--------------------------|--------------------------|
| Unitary Energy Savings (kWh/year) | Interior                 | Remote Ceiling or Wall-mounted | 201                      | 100                      |
|                                   |                          | Fixture Mounted or Wall Switch | 117                      |                          |
|                                   | Exterior                 |                                | 118                      | 134                      |

### 5.2.3 Peak Demand Savings

As part of the 2024-2025 Measure Assessment activities, the Evaluator reviewed the peak coincidence factor (PCF) of 60% for indoor lighting measures. This percentage constitutes the weighted average PCF of all indoor lighting measures installed in 2022 through Application Rebates and Small Business Energy Solutions (SBES) – another BNI program component of E1 – since no participant-specific information was available for Instant Rebates. In 2024, this value was maintained for indoor lighting measures, while a PCF of 100% was used for outdoor measures and circulator pumps since they are assumed to be in operation during the peak demand period. The unitary peak demand savings values for occupancy/motion sensors were also reviewed and updated in 2024. The tracked and evaluated values are presented in Table 18.

**Table 18: Instant Rebates Tracked and Evaluated Unitary Peak Demand Savings Values for Occupancy/Motion Sensors**

| Parameter                       | Type of Occupancy Sensor |                                | Tracked Value [W] | Updated Value [W] |
|---------------------------------|--------------------------|--------------------------------|-------------------|-------------------|
| Unitary Peak Demand Savings (W) | Interior                 | Remote Ceiling or Wall-mounted | 37.6              | 26.3              |
|                                 |                          | Fixture Mounted or Wall Switch | 21.9              |                   |
|                                 | Exterior                 |                                | 31.1              | 35.3              |

### 5.2.4 Interactive Effects

Interactive effects occur when the implementation of energy efficiency measures has an impact on the energy consumption of other elements such as heating and cooling; these are taken into account in the gross unitary savings equation presented in the 2024 tracking sheet. The interactive effects factors for the commercial sector are based on the same interactive effects as in previous years, as detailed in the 2024-2025 DSM MA.

## 5.2.5 Effective Useful Life

As part of the 2024-2025 DSM Measure Assessment activities, the Evaluator reviewed the EUL values used in the calculations of electrical energy savings that are expected to persist over time. In 2024, for LED linear fixtures, LED linear lamps, LED outdoor fixtures, and LED directional and architectural fixtures, EUL values were slightly adjusted as a result of the HOU value updates. For all other Instant Rebates measures, the EUL values established in the 2021 evaluation remained valid for the 2024 evaluation.

The tracked and evaluated EUL values are presented in Table 19.

**Table 19: Instant Rebates Tracked and Evaluated EUL Values**

| Measure                                                              | Tracked EUL (years) | Evaluated EUL (years) |
|----------------------------------------------------------------------|---------------------|-----------------------|
| <b>LED Linear Fixtures</b>                                           |                     |                       |
| 1 x 4 Luminaires                                                     | 11.6                | 11.9                  |
| 2 x 2 Luminaires and Retrofit Kits                                   | 11.6                | 11.9                  |
| 2 x 4 Luminaires and Retrofit Kits                                   | 11.6                | 11.9                  |
| Linear Ambient and Low-bay Luminaires                                | 11.6                | 11.9                  |
| Troffers                                                             | 20.9                | 21.4                  |
| <b>LED Linear Lamps</b>                                              |                     |                       |
| 2-foot Replacement Lamps                                             | 11.6                | 11.9                  |
| 3-foot Replacement Lamps                                             | 11.6                | 11.9                  |
| 4-foot Replacement Lamps                                             | 11.6                | 11.9                  |
| 8-foot Replacement Lamps                                             | 11.6                | 11.9                  |
| U-bend Lamps                                                         | 11.6                | 11.9                  |
| <b>LED Outdoor Fixtures</b>                                          |                     |                       |
| Outdoor Full-cut-off Wall-mounted Area Luminaires                    | 17.1                | 17.4                  |
| Flood and Spot Luminaires                                            | 17.1                | 17.4                  |
| Non-cut-off and Semi-cut-off Wall-mounted Area Luminaires            | 22.8                | 23.2                  |
| <b>LED Directional and Architectural Fixtures</b>                    |                     |                       |
| Track or Mono-point Directional Luminaires, LED Wall Wash Luminaires | 11.6                | 11.9                  |

The evaluated equivalent EUL values are applied to the gross and net first-year electrical energy savings of each measure to obtain gross and net lifetime electrical energy savings. As a result, the weighted average EUL values for gross and net savings differ (see Subsections 5.2.6 and 5.3.3 below). The gross weighted average EUL value is equal to 14.1 years.

## 5.2.6 Evaluated Gross Savings

The energy and peak demand savings associated with Instant Rebates were calculated using the unitary savings values (including baseline wattages, the actual wattages of efficient measures, ballast factors where applicable, interactive effects factors, PCFs, and ISRs for lighting measures) from the 2024-2025 DSM Measure Assessment. The savings at the generator were calculated using weighted average line loss factors determined based on the distribution of the rate code spending of other BNI programs in 2024. The line loss factors correspond to the values submitted to the Nova Scotia Utility and Review Board (NSUARB) as part of the 2014 Cost of Service Study Progress Update.<sup>11</sup>

The total savings established for each measure type are presented in Table 20 below.

| *The interactive effects factors for LED linear fixtures and LED linear lamps were drawn from the 2024-2025 DSM MA, adjusted by the proportions of LED recessed lamps and fixtures in the 2024 tracking sheet. |                     |                  |                      |                                            |                        |                                  |                  |                        |

Figure 9 below compares the tracked and evaluated gross energy savings, and Figure 10 further below compares the tracked and evaluated gross peak demand savings.

The slight differences between evaluated gross electrical energy savings and tracked savings were due to updated HOU for all LED measures and to updated unitary electrical energy savings for occupancy/motion sensors. Evaluated peak demand savings were almost identical to tracked values.

**Figure 9: 2024 Instant Rebates Tracked and Evaluated Gross Energy Savings at the Generator**

**Figure 10: 2024 Instant Rebates Tracked and Evaluated Gross Peak Demand Savings at the Generator**

As presented in Table 21, GHG emission reductions were calculated by applying the Nova Scotia-specific factor<sup>12</sup> for GHG emissions generated by electricity production to Instant Rebates gross savings.

**Table 21: Evaluated 2024 Instant Rebates Gross GHG Emission Reductions**

## 5.3 Net Savings

The Evaluator determined the net energy savings, i.e. the electrical energy savings that can be reliably attributed to a service, by estimating the NTGR. In the case of Instant Rebates, the NTGR is established by considering free-ridership.

### 5.3.1 Free-ridership

For Instant Rebates, free-ridership corresponds to the proportion of savings attributed to natural market trends. Thus, the free-ridership assessment is aimed at estimating the level of sales of energy efficient products that would have occurred in a market that evolved naturally, i.e. without service influence. To do so, a self-report approach that involved asking both participants and distributors sets of questions during telephone interviews was used. Participants were asked if they would have paid for the full cost of the products they bought and if they would have been of the exact same efficiency level and the same number of products. In addition, distributor influence was considered to capture midstream service influences on aspects like product promotion and stocking.

The algorithms used to assess participant free-ridership and distributor influence were updated in 2024 as part of the NTGR review. Both algorithms are presented in Appendix VI.

Free-ridership was assessed during the 2024 evaluation for the three main lighting measures:

- › LED linear fixtures
- › LED linear lamps
- › LED outdoor fixtures

These three categories represent 95% of all gross energy savings generated by Instant Rebates. They were selected because they were the best-selling product categories in 2024.

<sup>12</sup> At the time of writing, 2024 data were not yet available. The Nova Scotia-specific factor was obtained from Nova Scotia Power's 2023 total system emissions data (4,931,152 CO2 eq tonnes) and total electricity generation (10,442 GWh) was drawn from the following two sources: Nova Scotia Power, Total System Emissions, <https://www.nspower.ca/clean-energy/air-emissions-reporting> (last accessed September 27, 2024), and Emera Inc., Emera Inc. 2023 Annual Report, p. 31, available at [https://s25.q4cdn.com/978989322/files/doc\\_financials/2023/ar/Emera\\_2023\\_AR\\_FINAL.pdf](https://s25.q4cdn.com/978989322/files/doc_financials/2023/ar/Emera_2023_AR_FINAL.pdf) (last accessed September 27, 2024).

The Evaluator calculated the free-ridership level for each measure category, the results of which are presented in Table 22 below. The overall free-ridership levels take into account both the free-ridership levels obtained through the participant survey and the distributor influence levels measured through the distributor interviews. While average distributor influence levels are presented in the table for informational purposes, the average values were not used in the calculations of overall free-ridership levels; instead, the specific values obtained for each distributor were applied to each corresponding participant free-ridership value. First, free-ridership was calculated for each participant. Then, the distributor-specific influence value was applied to this such that the overall free-ridership level for each participant is the participant free-ridership level multiplied by (100% - Distributor influence level %); higher levels of distributor influence correspond to lower overall free-ridership levels.

**Table 22: 2024 Instant Rebates Free-ridership**

| Measure Category                                       | Average Distributor Influence Level<br>(from distributor interviews) | Free-ridership Level<br>(from participant survey) | Overall Free-ridership Level | Margin of Error |
|--------------------------------------------------------|----------------------------------------------------------------------|---------------------------------------------------|------------------------------|-----------------|
| LED Linear Fixtures                                    | 63%                                                                  | 16%                                               | <b>8%</b>                    | 3.7%            |
| LED Linear Lamps                                       | 59%                                                                  | 24%                                               | <b>15%</b>                   | 4.1%            |
| LED Outdoor Fixtures                                   | 61%                                                                  | 28%                                               | <b>15%</b>                   | 5.8%            |
| Sample sizes: n=10 distributors and n=50 participants. |                                                                      |                                                   |                              |                 |

The overall free-ridership levels obtained for each measure category range between 8% and 15%.

In 2022, overall free-ridership levels were 14% for LED linear fixtures, 27% for LED linear lamps, and 18% for LED outdoor fixtures. For all three measure categories, the overall free-ridership levels decreased in 2024 due to adjustments made to the application of both the intention score (which averages participants' cost, efficiency planning, quantity, and timing scores) and the influence score (which reflects the distributors' impact) in the free-ridership algorithm. Specifically, the 2024 update gave equal weight to both the intention and influence scores while the influence score only represented 20% to 33% of the weight in 2022. This adjustment made to the algorithm combined with influence scores in 2024 being overall lower<sup>13</sup> than intention scores resulted in decreased free-ridership levels. Additionally, lower free-ridership levels can also be attributed to the increased incentives offered in 2023 and 2024.

### 5.3.2 Net-to-gross Ratio

The NTGR is calculated using the following equation.

$$NTGR = (1 - \% \text{ Free-ridership})$$

As presented in Table 23, the NTGRs for the main measure categories were established using the free-ridership levels outlined in Subsection 5.3.1 above. For the other measures sold through Instant Rebates, a NTGR of 1.00 was used.

<sup>13</sup> A "low" influence score means that the program had higher influence on customer decisions to install efficient lighting. "Low" corresponds to low free-ridership levels. Similarly, "low" intention scores correspond to low free-ridership levels.

**Table 23: 2024 Instant Rebates NTGRs**

| Measure              | Free-ridership | NTGR |
|----------------------|----------------|------|
| LED Linear Fixtures  | 8%             | 0.92 |
| LED Linear Lamps     | 15%            | 0.85 |
| LED Outdoor Fixtures | 15%            | 0.85 |
| Other Measures       | 0%             | 1.00 |

### 5.3.3 Evaluated Net Savings

Net savings are defined as the changes in energy use that are specifically attributable to Instant Rebates. Net savings were estimated by applying the overall NTGR presented above to evaluated gross savings as exemplified in the following equation.

$$\text{Net Savings} = \text{Evaluated Gross Savings} \times \text{NTGR}$$

Net energy savings were first calculated separately for each measure category because NTGRs differed from one measure category to another.

Table 24 below presents the calculation details. The net energy savings resulted in 13,241 tonnes of CO<sub>2</sub> eq in net annual GHG emission reductions.

**Table 24: Evaluated 2024 Instant Rebates Net Energy and Peak Demand Savings**

| Measure Category                                            | LED Linear Fixtures | LED Linear Lamps | LED Outdoor Fixtures | LED Directional and Architectural Fixtures | Outdoor Motion Sensors | Indoor Occupancy /Motion Sensors | Circulator Pumps | Total for All Measures |
|-------------------------------------------------------------|---------------------|------------------|----------------------|--------------------------------------------|------------------------|----------------------------------|------------------|------------------------|

|                                                                                                                                 | Value         | Unit |       | Value       | Unit |                  |
| Energy Savings                                                                                                                  |               |      |       |             |      |                  |
| Tracked Savings by E1                                                                                                           | 32.251        | GWh  | 0.84  | 27.068      | GWh  | 104%             |
| Evaluation Results                                                                                                              | 31.327        | GWh  | 0.90  | 28.040      | GWh  |                  |
| Peak Demand Savings                                                                                                             |               |      |       |             |      |                  |
| Tracked Savings by E1                                                                                                           | 5.031         | MW   | 0.84  | 4.205       | MW   | 106%             |
| Evaluation Results                                                                                                              | 5.035         | MW   | 0.89  | 4.472       | MW   |                  |
| * The average NTGR values presented in this table correspond to the ratios of net savings to gross savings for Instant Rebates. |               |      |       |             |      |                  |

The evaluated net electrical energy and peak demand savings were respectively 4% and 6% higher than the values tracked by E1. While HOU values were slightly decreased as part of the 2024 evaluation, the increases in both unitary energy and peak demand savings for indoor (fixture-mounted or wall-switch) and outdoor occupancy/motion sensors along with the updated increase to NTGRs for LED linear fixtures, LED linear lamps, and LED outdoor fixtures resulted in evaluated savings exceeding the tracked values.

## 6 Overall BER Results

As outlined in Figure 11, BER nearly reached the planned net electrical energy savings, falling short by less than 1%, and exceeded the peak demand savings target by 13%

**Figure 11: 2024 BER Targets and Evaluated Savings**

Table 26 compares the savings tracked by E1 to the 2024 evaluated savings for BER along with the corresponding realization rates.

**Table 26: Comparison of 2024 BER Tracked and Evaluated Savings at the Generator**

|                                                                                                                                                                                                            | Gross Savings |      | NTGR* | Net Savings |      | Realization Rate |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|------|-------|-------------|------|------------------|
|                                                                                                                                                                                                            | Value         | Unit |       | Value       | Unit |                  |
| Energy Savings                                                                                                                                                                                             |               |      |       |             |      |                  |
| Tracked Savings by E1                                                                                                                                                                                      | 47.777        | GWh  | 0.81  | 38.557      | GWh  | 103%             |
| Evaluation Results                                                                                                                                                                                         | 46.852        | GWh  | 0.84  | 39.529      | GWh  |                  |
| Peak Demand Savings                                                                                                                                                                                        |               |      |       |             |      |                  |
| Tracked Savings by E1                                                                                                                                                                                      | 6.752         | MW   | 0.81  | 5.479       | MW   | 105%             |
| Evaluation Results                                                                                                                                                                                         | 6.756         | MW   | 0.85  | 5.746       | MW   |                  |
| *Different NTGRs were established for Application Rebates and Instant Rebates. The average NTGR values presented in this table correspond to the ratios of net savings to gross savings for both services. |               |      |       |             |      |                  |

The evaluated net electrical energy and peak demand savings established through this evaluation were respectively 3% and 5% higher than the values calculated in the 2024 tracking sheet. For the most part, the differences are attributed to unitary savings value and NTGR updates for Instant Rebates.

## 7 BER Market Evolution

E1 has been active in the LED market of the BNI sector through BER since 2010. Market evolution assessments were completed as part of the 2017, 2018, 2019, and 2021 evaluations, the results of which served to analyze key market indicators and present a technology diffusion curve illustrating the market adoption of LED lighting in the Nova Scotia BNI sector. The aim of this section is to update the data collected as part of previous evaluations and provide up-to-date insights regarding the market evolution of LED lighting in Nova Scotia. Given that the LED market is rapidly evolving, regularly monitoring barriers to LED adoption is important to enable E1 to adapt the BER offer, if needed.

### 7.1 Sales of LED Lighting Technologies

#### 7.1.1 BER-IR Incented LED Products

The total number of LED lamps and fixtures per measure category incented through Instant Rebates since 2020 is presented in Figure 12 below. The Evaluator considers that sales through BER represent an acceptable reflection of overall LED market trends given that not only are there no application requirements, meaning any business in the province of Nova Scotia can participate in the program component by simply purchasing eligible products, but also distributor partners have locations throughout the province, thus ensuring strong geographical coverage.

While the total number of rebated LED linear fixtures and LED linear lamps rebated through Instant Rebates increased between 2022 and 2023, participation in both categories decreased by 10% and 41% respectively in 2024. LED linear fixtures constituted 46% and LED linear lamps comprised 48% of all BER rebated LED lighting products in 2024, the remaining 6% being LED outdoor fixtures. While the proportion of LED outdoor fixtures has remained stable since 2020, the proportion of LED linear fixtures has been increasing over LED linear lamps compared to 2023 when they respectively represented 37% and 59% of all BER rebated LED lighting products.

**Figure 12: BER Instant Rebates Incented LED Units, 2020-2024**

## 7.1.2 BER-IR LED Purchasing Decisions

The Evaluator conducted a participant survey, including both contractors and end users, to understand the LED purchasing decisions of participants. Most participants (78%) reported that they had purchased efficient lighting products to replace existing fixtures or lamps, while two in 10 (20%) said they had purchased the efficient products for new constructions. Of those who purchased efficient products to replace their existing fixtures or lamps, close to one-third (34% of all participants surveyed) said their existing fixtures or lamps were working but at the end of their useful life, while one in four (22% of all participants surveyed) said their existing fixtures or lamps were broken. Only 10% said their existing products were working and not close to the end of their useful life, and the same proportion (10%) said that some were working and some were not working. Therefore, in a majority of cases (86%), participants would have had to purchase new lamps or fixtures in the absence of the service. Figure 13 below shows the breakdown between the participants who reported they had decided to purchase LED lighting products for new construction projects, and the different conditions of the existing fixtures or lamps, when LEDs were purchased for replacement.

**Figure 13: Breakdown Between New Construction and Replacement of Existing Lighting**

## 7.2 Evolution of LED Versus Non-LED Lighting Products

To understand the availability of LED versus non-LED products in Nova Scotia, the Evaluator asked BER-IR distributors what proportion of their 2024 lighting stock was LED versus non-LED for each product category. Distributors were then asked how they expected their forecasted lighting sales to evolve in the next two years. The Evaluator considers that interviewed BER-IR distributors represent an acceptable reflection of the overall market in Nova Scotia given that they represented 92% of LED lighting products sold through BER-IR in 2024 and that it was assumed that the majority, if not all, of distributors in the province participate in BER-IR to remain competitive.

Overall, distributors reported carrying a large majority of LED lighting products, reporting on average that 96% of all their lighting stock were LEDs. Distributors reported higher proportions of LED fixtures in their inventories, reporting 100% for linear fixtures and high-bay fixtures and 99% for outdoor fixtures. This is up from the 92% share of fixture shipments estimated using Electro Federation Canada data for the Atlantic region as part of the 2021 evaluation. Distributors reported that the large majority of lamp stock was also LED, and this proportion is expected to grow by 2026. The results are presented in Figure 14 below.

**Figure 14: 2024 LED Versus Non-LED Business Lighting Stock and Expected Evolution**

Distributors reported that finding non-LED linear fixtures is increasingly difficult. Moreover, four distributors said that this is due to suppliers no longer manufacturing or making non-LED or traditional fixtures available. One of these distributors stated that “manufacturers have switched to LED”, with another reporting, “we can’t find anything but LED fixtures at this point from our manufacturers, with few small exceptions”. One distributor also commented that clients no longer ask for non-LED linear fixtures. These findings were largely echoed for high-bay fixtures.

For outdoor fixtures, three distributors reported that they had a very small amount of non-LED stock (1-2%), with two reporting that this is due to old stock being used up over time. One distributor again mentioned that the availability of non-LED outdoor fixtures is limited due to manufacturers.

Very few distributors reported carrying non-LED fixtures at all, and the small quantities of linear, outdoor, and high-bay fixtures they have in stock are either because products have been discontinued or they carry replacement products for a few customers who have not switched to LED technology.

LED linear lamps make up a large majority of stock that is expected to grow in the next two years, but unlike fixtures, the responses of distributors on their proportion of LED linear lamps varied. A total of seven out of the 10 interviewed distributors reported that over 90% of their stock was LED, with the remaining three estimating that LEDs make up between 50- 75% of their stock. Several distributors mentioned that their sales of linear lamps are decreasing overall as more clients shift to integrated LED fixtures, which is also reflected in the LED sales presented in Figure 14 above. Another distributor mentioned increased LED offerings driving them to carry more LED linear lamps. Similar trends were noted for outdoor replacement lamps and high-bay lamps from those distributors that carry these products.

For replacement lamps, many distributors still carry non-LED lamps, whether linear, outdoor, or high-bay, to meet the needs of institutional and government customers and, to a lesser extent, property management companies. One distributor mentioned that there are no LED alternatives for some linear lamps, such as high output lamps used for signage, and that non-LED replacement lamps are sometimes used in difficult-to-access environments in which upgrading the fixtures cannot be easily done.

Nevertheless, distributors expect LED lamps to make up 94-98% of their stock by 2026 depending on the lamp type. The proportion of lamps that are LED is anticipated to increase in the next two years as discontinued non-LED products currently in stock are sold or removed from inventories.

Distributors reported that the LED market is relatively stable at this stage. All 10 interviewed distributors do not expect big changes in the overall proportion of LED stock in the absence of BER-IR. One distributor noted the different quality and efficiency of LED technologies available and that the service should look to incent the best LED technology within a given category. The service has impacted the evolution of the market in Nova Scotia, and two distributors reported unaided that BER-IR, notably the rebates offered, has helped move the market to where it is today.

In terms of LED availability, most distributors mentioned the supply chain has been stable. Also, one distributor mentioned that North American lighting manufacturers have had to strengthen their capacity to effectively compete with increased offerings from low-cost resellers, and one distributor believed that the popularity of just-in-time inventory management (due to high warehousing costs) has had a negative impact on product availability in recent years.

### **7.2.1 DesignLights Consortium (DLC) Certified Fixtures**

Distributors were asked about the breakdown of the LED fixtures between DLC Standard Certified, DLC Premium, and non-certified products. Of the six distributors that were asked those questions, four were able to provide an estimate of the breakdown of their stock. The six respondents represented 73% of LED lighting products sold through BER-IR in 2024. Three of these distributors reported that the majority of their fixture stock (80% or higher) was DLC Premium. The other distributor reported that the majority of their stock is DLC Standard Certified (80%), followed by Premium (15%). Three distributors carry a small stock of non-certified products (ranging from 5-20%), with the other not carrying any.

The other two distributors were unable to provide a breakdown of their stock, although they provided details about their stock. One reported not carrying inventory, instead making orders based on individual project needs, but mentioned that the choice of product is always DLC certified, and project needs dictate whether Standard or Premium is chosen. The other was unable to provide a breakdown yet mentioned that, if they bring in stock, it is always DLC certified, in part to ensure products qualify for a BER rebate.

In addition, three distributors out of the four who provided a breakdown of their stock believe the share of DLC certified fixtures is relatively stable and would remain so even in the absence of E1 rebates. One distributor noted that this is because the price of DLC Premium is continually decreasing while availability is increasing. Another stated that they choose products based on performance. Hence, while the

rebates are important, it is less important than product performance. Another stated that manufacturers all certify products to meet DLC Premium standards “...it is now the standard practice in the industry, so most reputable companies are certifying.” On the other hand, one distributor would expect a large shift from DLC certified to uncertified products without the rebates due to cost differences between the products.

In terms of pricing, for distributors that carry uncertified LED fixtures (n=4), they reported that, once the rebate is applied to DLC certified fixtures, prices are lower than (n=3) or comparable (n=1) to those of uncertified products. Similarly, for the five that carry DLC Premium, they reported that once the rebate is applied to DLC Premium products, prices are lower than (n=3) or comparable (n=2) to those of uncertified LED fixtures.

## 7.3 Average Pricing for LED Lamps and Fixtures in BER-IR

### 7.3.1 LED Lighting Costs

#### Retail Prices

Figure 15 below illustrates the evolution of the average cost per unit (before rebates) from 2020 to 2024 for LED linear lamps and fixtures as well as LED outdoor fixtures rebated through BER-IR. The data were drawn from the BER-IR tracking sheets.

Since 2020, the average retail prices of LED linear fixtures and linear lamps have remained relatively stable, reaching \$77.55 and \$8.54 respectively in 2024. For LED outdoor fixtures, the average retail price dropped in 2021 and has remained steady since at \$164.80 in 2024. Averages are provided to show an overall trend in prices only. Precise values should be interpreted with caution as there is a high range of prices observed across each category.

**Figure 15: Average Retail Prices of IR Rebated LED Lamps and Fixtures, 2020-2024**

## Rebate Values

As outlined in Table 27, the average rebate values under Instant Rebates have remained relatively steady for all measure categories since 2022. This is in part due to E1 capping incentives either at a set maximum amount per unit based on price or at 75% of the unit price, whichever is lowest.

**Table 27: Average Rebate Values Under Instant Rebates for LED Linear Fixtures and Lamps and LED Outdoor Fixtures, 2020-2024**

| Measure Category     | 2020    | 2021    | 2022    | 2023    | 2024    |
|----------------------|---------|---------|---------|---------|---------|
| LED Linear Fixtures  | \$23.35 | \$26.37 | \$38.00 | \$40.11 | \$40.67 |
| LED Linear Lamps     | \$3.71  | \$3.69  | \$4.43  | \$4.94  | \$4.52  |
| LED Outdoor Fixtures | \$49.10 | \$57.89 | \$66.51 | \$66.62 | \$68.11 |

## 7.4 New Technologies and Product Offerings

When asked about new technologies and LED product offerings, distributors have seen increases in available multi-wattage and multi-voltage fixture products, which means that they are able to carry a smaller assortment of lamps and fixtures while continuing to meet customer demand. Econoler noted that multi-wattage products are not easily identifiable in the BER-IR tracking sheet and that tracked wattages may not necessarily be the wattages used in all instances. Lamp technology has also improved, albeit more slowly. Controls have continued to improve over the past three years, notably for colour changing technology for which there is a wider range of choices, especially in colour temperature and lumen outputs, along with better Bluetooth technology in fixtures and better dimming capabilities. One distributor also noticed a better assortment of decorative fixtures for different applications (e.g. ultra flexible rope lighting that can be tied into a bow or fixtures and lamps with an integrated emergency power source).

## 7.5 Codes and Standards

A major indicator of market transformation is the adoption of more stringent codes and standards. Currently, the following products are regulated:

- › Fluorescent lamp ballasts
- › General service fluorescent lamps
- › Metal halide lamp ballasts
- › General service lamps and modified spectrum incandescent lamps
- › General service incandescent reflector lamps

The first two products above relate to linear fixtures and lamps rebated through BER. Regulations for these products were last updated in 2016 when new requirements for higher fluorescent lamp and ballast efficiency were aimed at effectively banning T12 fluorescent tubes. The metal halide lamp ballast regulation applies to non-linear fixtures (primarily outdoor or high-bay fixtures) and, as is the case for the fluorescent lamp regulation, allows inefficient fixtures below the baseline currently used by BER-IR. The latest regulation update in Canada, Amendment 18, primarily impacts non-linear lamps (general service lamps and general service incandescent lamps), which is not relevant to the baseline used for the products sold in BER-IR.

This analysis of lighting standards indicates that, while there is some movement in Canadian regulations with respect to advancing lighting energy efficiency, the market is driving the shift to LED technologies more than regulations.

## 7.6 Market Evolution Summary

In their recommendations on market transformation and market effects, Rosenberg and Hoefgen (2009) identify a number of factors, listed in Table 28 below, to be analyzed to identify whether program support should be withdrawn or reduced in light of changes observed in the market.<sup>14</sup>

**Table 28: 2024 Analysis of Key Factors in Market Evolution**

| Factor                                                   | Results                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Market share of LED fixtures for BNI sector              | The fixtures market is fully transformed to LED; distributors report that all or nearly all of their fixture stock is LED and finding non-LED fixtures is very difficult. This is the case for linear, outdoor, and high-bay fixtures.                                                                                                                                                                                             |
| Market share of LED lamps for BNI sector                 | The lamp market lags the fixture market somewhat, although LED products still represent upward of 87-95% of the stock depending on the lamp type, and distributors predict that LED lamps will represent 94-96% of the stock by 2026. A moderate inventory of non-LED lamps is carried by distributors to meet the need of institutional, government, and property management customers who have not yet upgraded to LED fixtures. |
| Trends in prices and availability                        | According to program data, pricing for LED products has been relatively stable over the last three years. While distributors report that the LED market is relatively stable, there are still differences among LED products in terms of quality and efficiency. Distributors report carrying the majority of DLC certified products as opposed to uncertified products.                                                           |
| Likelihood of inclusion in a near-term code or standard  | The efficiency levels of LED linear fixtures and lamps rebated through BER remain superior to the efficiency levels required by current Canadian regulations.                                                                                                                                                                                                                                                                      |
| Market readiness of more efficient substitute technology | No more efficient substitute to LEDs has come to market. Efficiency improvements in LED lamps and fixtures are likely with organizations like the DesignLights Consortium increasing their criteria for certification.                                                                                                                                                                                                             |

Figure 16 below provides a qualitative indication of the stage of LED lighting adoption in the Nova Scotia BNI sector. The technology diffusion curve in the table illustrates how successive groups of customers, from “innovators” to “laggards”, adopt a new technology (as illustrated by the innovation adoption curve in blue)<sup>15</sup> and how market penetration (illustrated by the S-curve in green) eventually reaches 100% saturation levels. The figure does not specifically correlate with distributor stocking, more details on that topic is discussed in Section 7.1 above. The market penetration of the LED commercial lighting market in Nova Scotia is illustrated by the green box. The Evaluator finds that the BNI LED fixture market has reached maturity with some potential to target laggards to move to LED fixtures. The LED lamp market is mature and levelling off as more and more fixtures are integrated. Both product markets are evolving toward more multi-mode models.

<sup>14</sup> Rosenberg and Hoefgen, Market Effects and Market Transformation: Their Role in Energy Efficiency Program Design and Evaluation, prepared for the California Institute of Energy and the Environment, 2009.

<sup>15</sup> Everett M. Rogers, Diffusion of Innovations – Fifth Edition, August 16, 2003.

Figure 16: 2024 Market Evolution for Commercial LED Lighting

To supplement the above market evaluation results, the Evaluator also conducted a jurisdictional scan to investigate similar programs to BER-IR. The Evaluator found very few examples of instant discount programs targeted at the BNI sector. For details, please see Appendix VII.

## 8 BER Key Findings and Recommendations

The main objectives of the 2024 BER evaluation were as follows:

- › Collect information on participant and distributor perspectives
- › Calculate gross and net BER results (for both AR and IR), namely first-year and lifetime electrical energy savings, peak demand savings, as well as avoided GHG emissions
- › Analyze the evolution of the BNI lighting market

This section provides the Evaluator's key findings and recommendations in relation to these objectives.

**2024 BER-Finding: BER almost achieved its net electrical energy savings target, falling short by less than 1%, while exceeding its net peak demand savings target by 13%.**

BER achieved 39.529 GWh in net electrical energy savings and 5.746 MW in net peak demand savings at the generator in 2024, thus almost reaching the planned net electrical energy savings of 39.747 GWh, falling short by less than 1%, and exceeding the planned net peak demand savings of 5.107 MW by 13%.

**2024 BER-Finding: In 2024, Instant Rebates participation decreased by 26% compared to 2023 levels. Application Rebates participation increased by 18% in 2024, with gross energy savings per participant increasing by 16% compared to 2023 levels.**

In 2024, Instant Rebates participation decreased by 26% due to fewer measures rebated. Conversely, Application Rebates participation increased with 18% more participating businesses and with net savings per participant also increasing 16% compared to 2023. Overall, BER gross energy savings and peak demand savings decreased by 2% and 9% respectively between 2023 and 2024. This was mainly due to the decrease in Instant Rebates savings generated by LED linear lamps and LED linear fixtures.

**2024 BER Finding: Overall satisfaction with BER Instant Rebates is high among both participants and distributors.**

For Instant Rebates, average satisfaction ratings of 9.1 and 8.3 out of 10 were reported by participants and distributors respectively. Participants reported being very satisfied with the interaction and communication with distributors and with the rebate amounts (average ratings of 9.0). Distributors were highly satisfied with the service support and communications provided by E1 (average rating of 9.3) and were generally satisfied with rebate processing, tracking, and reporting (average rating of 8.4).

**2024 BER Finding: The Instant Rebates free-ridership algorithm was updated in 2024 and the overall free-ridership levels established in the evaluation ranged between 8% and 15%.**

The Evaluator reviewed and updated the Instant Rebates free-ridership algorithm to give equal weight to the intention score (which averages cost, efficiency planning, quantity, and timing scores) and the influence score. The 2024 evaluation results represent a decrease from the 2022 evaluation; moreover, caution must be taken when comparing free-ridership results between these evaluations since they were established using different approaches. Additionally, lower free-ridership levels can also be attributed to the increased incentives offered in 2023 and 2024.

**2024 BER-Finding:** Both evaluated net electrical energy savings and peak demand savings were identical to the values tracked by E1 for Application Rebates. Evaluated net electrical energy and peak demand savings were both higher by 4% and 6% respectively than tracked results for Instant Rebates.

Overall, evaluated BER net electrical energy and peak demand savings established through this evaluation were both respectively 3% and 5% higher than those calculated in the 2024 tracking sheet. The differences are attributed to Instant Rebates because of updates to unitary savings values and NTGRs.

**2024 BER-Finding:** According to participating BER-IR distributors, the fixture market has been transformed to LED. Distributors indicate that non-LED options for fixtures are now rare, reporting that their entire stock of fixtures is LED.

Distributors reported that 100% of their stock was LED for linear and high-bay fixtures and 99% for outdoor fixtures. They reported that manufacturers no longer supply non-LED alternatives and that this market share would be stable even in the absence of E1 incentives.

**2024 BER-Finding:** Most purchases rebated through BER-IR are for new construction or products at the end of their useful life, which validates the use of a replace-on-burnout baseline for this program component.

**2024 BER-Finding:** The market evaluation results indicate that the market practice for BNI fixtures is LED technology, indicating that an update to the baseline for fixtures sold through BER-IR is imminent.

**Recommendation #1:** Undertake additional research to further validate the market evaluation results to establish, no later than Q3, when the LED baseline for BER-IR LED fixtures should take effect. Research should focus on the potential risk of the fixture market rebounding from reducing or removing the Instant incentives in the Nova Scotia market.

**2024 BER-Finding:** The LED market practice baseline for BNI fixtures also applies to new construction projects incented through BER-AR.

**Recommendation #2:** Review the eligibility criteria for LED lighting in new construction projects in BER-AR given evidence that LEDs are the baseline for this market.

**2024 BER-Finding:** Distributors reported that the majority of their fixture stock is either DLC Premium or DLC standard.

Some distributors carry a small portion of non-certified product, although the majority is DLC certified. Most distributors expect that the market would remain certified products even in the absence of E1 incentives. This should be monitored going forward.

**Recommendation #3:** In line with Recommendation #1, research should also investigate the efficiency level of an LED baseline for LED fixtures.

**2024 BER-Finding:** Distributors still carry a small percentage of non-LED lamps for a subset of customers. They forecast this share to diminish even more over the next two years as more fixtures are replaced with LEDs.

**Recommendation #4:** The current non-LED baseline for lamps should be maintained for BER-IR and reassessed in 2026. Given trends, E1 should plan for a baseline change starting in 2027.

**2024 BER-Finding:** Lighting retrofit opportunities remain for early replacements and particularly in some subsectors where capital funding is limited, like institutional and government buildings and to a lesser extent property management companies.

**Recommendation #5:** Plan for a shift in the product offer for LED fixtures from BER-IR to BER-AR to capture remaining retrofit opportunities once LED baseline is adopted for BER-IR.

**Recommendation #6:** Focus efforts on BER-AR to target market laggards for early replacement retrofits of their lighting.

**Recommendation #7:** A LED baseline should also be applied to the EUL of LED fixtures rebated through BER-AR and SBES to reflect the fact that existing fixtures would have been replaced with LED fixtures at the end of their life. The baseline should consider the proportion of projects targeted for early replacement versus replace on burn-out as well as an estimated remaining EUL.

**2024 BER-Finding:** Distributors report that control products continue to evolve.

**Recommendation #8:** Analyze opportunities for increasing interest around controlled lighting products.

**2024 BER-Finding:** There is an increase in multi-wattage and multi-voltage fixture products available on the market.

For these products, the tracked wattage may not necessarily be the wattage used for all applications.

**Recommendation #9:** Ensure that multi-wattage products are identified in the tracking sheet. Update applications for BER-AR and SBES to identify multi-wattage products and confirm the wattage being used. Select the middle wattage (i.e. not the lowest or highest) as the tracked wattage when information is not available from the participant.

## CONCLUSION

Table 29 presents the participation levels, net-to-gross ratios (NTGRs), evaluated gross and net savings at the generator, annual GHG emission reductions, as well effective useful life (EUL) values for each service and Efficient Product Rebates as a whole.

**Table 29: Overall 2024 Efficient Product Rebates Participation and Evaluated Savings**

|                                                                                                                                                             | Participation Level |               | Gross Savings |                  | NTGR   | Net Savings |                  |

| Peak Demand Savings                                                                                                                                         |                     |               | 6.756         | MW               | 0.85   | 5.746       | MW               |
| Annual GHG Emission Reductions                                                                                                                              |                     |               | 22,124        | Tonnes of CO2 eq | 0.84   | 18,666      | Tonnes of CO2 eq |
| EUL                                                                                                                                                         |                     |               | 15.7          | Years            |        | 15.4        | Years            |
| * The average NTGR values presented in the total correspond to the ratios of net savings to gross savings for both Application Rebates and Instant Rebates. |                     |               |               |                  |        |             |                  |

Figure 17 and Figure 18 below illustrate the net electrical energy and peak demand savings targets for the overall Efficient Product Rebates program and indicate whether targets were achieved in 2024. Efficient Product Rebates was aimed at achieving 39.747 GWh in net electrical energy savings and 5.107 MW in net peak demand savings at the generator for 2024. The program nearly reached the planned net electrical energy savings, falling short by less by 1%, and exceeded the peak demand savings target by 13%. Instant Rebates was the largest contributor to total program net electrical energy and peak demand savings.

## Introduction

### A. INTRODUCTION A – Business with a contact name

Could I speak with <INSERT NAME>?

1. Yes [CONTINUE]
2. No [SAY “PERHAPS YOU CAN HELP ME ANYWAY.” GO TO INTRODUCTION B]

Hello, I am with Narrative Research, and we are conducting an evaluation of energy efficiency services provided by Efficiency Nova Scotia. We have a few questions about your recent experience with Efficiency Nova Scotia’s Business Energy Rebates Program through which you or your organization recently purchased rebated <EFFICIENT PRODUCT> at a participating distributor. More precisely, we are referring to the purchase of <QUANTITY SOLD> <PRODUCT BRAND> <EFFICIENT PRODUCT> made in <MONTH OF PURCHASE> through <DISTRIBUTOR>, for which you received a rebate of <REBATE AMOUNT>.

- A1. Are you the person in your organization who is most knowledgeable about the decision to purchase these <EFFICIENT PRODUCT> from <DISTRIBUTOR> in 2024?
1. Yes [GO TO A3]
  2. No [GO TO A2]
- A2. Is there someone else in your organization who would know about the decision to purchase these <EFFICIENT PRODUCT>? [PROBE IF UNSURE: This person may be an engineer, equipment contractor, or utility account manager].
1. Yes [ASK for name: \_\_\_\_\_ and telephone #: \_\_\_\_\_] [ASK TO SPEAK TO THAT PERSON AND RESTART AT INTRODUCTION. IF OTHER PERSON IS UNAVAILABLE, THANK, TERMINATE, RECORD DATA AND SCHEDULE INTERVIEW WITH BEST CONTACT]
  2. No [THANK & TERMINATE AND RECORD DATA]
- A3. Did you purchase these products for your own organization, or are you a company purchasing products for a customer or project outside of your organization? [SINGLE RESPONSE]
1. I purchased the products for my organization
  2. I purchased the products for a customer or project outside of my organization/I am a contractor
  3. Other, please specify [IF BOTH, SELECT OPTION 1]
  98. Don’t know
  99. Refused

- A4. To help Efficiency Nova Scotia improve the Business Energy Rebates program, would you have a few minutes to answer questions about your organization's participation in the program?

**(IF NEEDED:** The survey will take about 10 minutes to complete. )

**(IF NEEDED:** You may have recently been contacted by Narrative Research or by an Efficiency Nova Scotia representative about your experience with the service. This survey is different as it focuses on other aspects of your participation in the service.)

1. Yes **[CONTINUE]**
2. No **[ASK "CAN WE SCHEDULE A MORE CONVENIENT TIME FOR YOU TO CONDUCT THIS SURVEY?"] [IF NO, THANK, TERMINATE AND RECORD DATA] [IF YES, SCHEDULE CALLBACK]**

## **B. INTRODUCTION B – Business with no contact name**

Hello, I am with Narrative Research, and we are conducting an evaluation of energy efficiency services provided by Efficiency Nova Scotia. We have a few questions about your recent experience with Efficiency Nova Scotia's Business Energy Rebates Program through which you or your organization recently purchased rebated **<EFFICIENT PRODUCT>** at a participating distributor. More precisely, we are referring to the purchase of **<QUANTITY SOLD> <PRODUCT BRAND> <EFFICIENT PRODUCT>** made in **<MONTH OF PURCHASE>** through **<DISTRIBUTOR>**, for which you received a rebate of **<REBATE AMOUNT>**.

- B1. Could you help us identify the person who is most knowledgeable about the decision to purchase these products? **[PROBE IF UNSURE:** This person may be an engineer, equipment contractor, or utility account manager].
1. Yes, the person is **[RECORD NAME AND TELEPHONE NUMBER AND ASK TO SPEAK TO THIS PERSON – GO BACK TO INTRO A]**
  2. Yes, but the person is unavailable **[RECORD NAME AND TELEPHONE NUMBER. THANK AND TERMINATE; SCHEDULE CALL BACK TO SPEAK TO THAT PERSON]**
  3. No **[THANK, TERMINATE AND RECORD DATA]**

## **C. Participation and Decision to Purchase**

- C1. **[ASK IF CONTRACTOR A3=2]** Who usually makes the decision to buy **<EFFICIENT PRODUCT>** rather than standard **<STANDARD PRODUCT>**? Is it... **[READ CODE 1-2 AND 96. SINGLE RESPONSE]**.
1. You or someone else in your organization
  2. Your customer
  96. Someone else (SPECIFY: \_\_\_\_\_)
  98. (Don't know)

C2. **[ASK IF END-USER A3=1 OR C1=1]** Can you describe the main activity of your organization? **[DO NOT READ BUT CONFIRM WITH RESPONDENT THAT THE CATEGORY YOU CHOOSE IS CORRECT]**

1. (Agriculture)
2. (Banking)
3. (Education)
4. (Health Care)
5. (Hospitality)
6. (Manufacturing/Industrial)
7. (Office/Commercial)
8. (Public Service)
9. (Residential)
10. (Restaurant/Bar)
11. (Retail)
12. (Technology/Science)
13. (Warehouse / storage)
96. (Other (SPECIFY: \_\_\_\_\_))
98. (Don't know)
99. (Refused)

C3. **[ASK IF C1=2]** Before making the decision to purchase <EFFICIENT PRODUCT>, do customers usually ask for your advice? **[SINGLE RESPONSE]**

1. Yes **[GO TO C7]**
2. No **[GO TO C9]**
98. Don't Know **[GO TO C9]**
99. Refused **[GO TO C9]**

C4. **[ASK IF A3=1, C1=1 OR C3=1]** Now, I would like to understand your decision-making process for selecting LED lighting. Did you consider any alternatives to <EFFICIENT PRODUCT> before making your purchase decision? **[SINGLE RESPONSE]**

1. Yes
2. No
98. (Don't know)
99. (Refused)

- C5. **[ASK IF A3=1, C1=1 OR C3=1 AND <LINEAR LAMP>]** What lighting alternatives did you consider? **[DO NOT READ, ACCEPT MULTIPLE RESPONSES]**
1. Standard LED
  2. Incandescent lighting
  3. Fluorescent lighting
  4. Halogen lighting
  5. Other lighting (specify)
  98. (Don't know)
  99. (Refused)
- C6. **[ASK IF A3=1, C1=1 OR C3=1 AND <LINEAR OR OUTDOOR FIXTURE>]** What alternatives to LED fixtures did you consider? **[DO NOT READ, SINGLE RESPONSE]**
1. Keep existing fluorescent fixture
  2. Change for another fluorescent fixture
  3. Other (specify)
  98. (Don't know)
  99. (Refused)
- C7. **[ASK IF A3=1, C1=1 OR C3=1]** What was the SINGLE most important reason you purchased **<EFFICIENT PRODUCT>** rather than standard **<STANDARD PRODUCT>**? **[DO NOT READ. SINGLE RESPONSE.]**
1. Availability of other alternatives
  2. Energy efficiency
  3. Cost savings
  4. Lifespan
  5. Efficiency Nova Scotia program incentives
  6. Environmental cause
  7. Contractor influence
  8. Distributor influence
  96. (Other (SPECIFY: \_\_\_\_\_))
  98. (Don't know)
  99. (Refused)

- C8. **[ASK IF A3=1, C1=1 OR C3=1; DO NOT ASK IF 98 OR 99 IN C4]** What was the SECOND most important reason you purchased <EFFICIENT PRODUCT> rather than standard <STANDARD PRODUCT>? **[DO NOT READ. SINGLE RESPONSE.]**
1. Availability of other alternatives
  2. Energy efficiency
  3. Cost savings
  4. Lifespan
  5. Efficiency Nova Scotia program incentives
  6. Environmental cause
  7. Contractor influence
  8. Distributor influence
  96. (Other (SPECIFY: \_\_\_\_\_))
  97. No other reason
  98. (Don't know)
- C9. **[ASK ALL]** Did your distributor recommend <EFFICIENT PRODUCT> to you? **[SINGLE RESPONSE]**
1. Yes
  2. No
  98. (Don't know)
  99. (Refused)
- C10. For what type of project did you purchase the <EFFICIENT PRODUCT>? Was it for a... **[READ. SINGLE RESPONSE]**
1. New construction
  2. Replacement of existing fixtures or lamps
  98. (Don't know)
  99. (Refused)
- C11. **[ASK IF C10=2]** In what state were the existing fixtures or lamps when you decided to purchase the <EFFICIENT PRODUCT>? Were they... **[READ. SINGLE RESPONSE]**
1. Working but at the end of their useful life
  2. Working and not close to the end of their useful life
  3. Broken
  4. **[DO NOT READ]** (Some were working, some were not working)
  96. **[DO NOT READ]** (Other (SPECIFY: \_\_\_\_\_))
  98. (Don't know)
  99. (Refused)

## D. Free-Ridership

- D1. **[ASK ALL]** Were you aware that you received a rebate when purchasing these **<EFFICIENT PRODUCT>?** **[SINGLE RESPONSE]**
1. Yes
  2. No
  98. (Don't know)
- D2. **[ASK IF D1=2 OR 98]** Have I understood correctly that you were not aware that a rebate would be given on the product's total cost when you purchased these items? **[DO NOT READ. SINGLE RESPONSE]**
1. Yes, correct (unaware of the rebate)
  2. No, incorrect (aware of the rebate)
  98. Don't know
  99. Refused
- D3. **[ASK IF D1=1 OR D2=2]** Were you aware that the rebate was offered by Efficiency Nova Scotia? **[SINGLE RESPONSE]**
1. Yes
  2. No
  98. Don't know
- D4. **[ASK IF END-USER A3=1 AND D3=1]** How did you first become aware of the rebates available from Efficiency Nova Scotia's Business Energy Rebates Program? **[DO NOT READ. SINGLE RESPONSE]**
1. Through my contractor
  2. Through my distributor
  3. Efficiency Nova Scotia staff contacted me about the program
  4. Efficiency Nova Scotia website
  5. Efficiency Nova Scotia promotion
  6. Past experience with another Efficiency Nova Scotia program
  7. Word of mouth from other organizations/businesses/Friends/Family
  8. Online - general
  96. Other, please specify
  98. Don't know
  99. Refused

D5. **[ASK ALL]** Had you *already* decided to purchase these <EFFICIENT PRODUCT> *before* talking to a distributor? **[SINGLE RESPONSE]**

- 1. Yes
- 2. No
- 98. (Don't know)
- 99. (Refused)

D6. **[ASK IF AWARE (D1=1 or D2=2)]** Had you *already* decided to purchase these <EFFICIENT PRODUCT> *before* knowing that these efficient products were rebated? **[SINGLE RESPONSE]**

- 1. Yes
- 2. No
- 98. (Don't know)
- 99. (Refused)

D7. **[ASK ALL]** Efficiency Nova Scotia offered a rebate for the purchase of efficient lighting products. If your organization had not received the rebate and the cost of <EFFICIENT PRODUCT> had been about <REBATE AVERAGE VALUE BY CATEGORY> higher per unit, what is the likelihood you would have paid the full cost of the <EFFICIENT PRODUCT>? **[SINGLE RESPONSE]**

- 1. Definitely would have
- 2. Probably would have
- 3. Probably would not have
- 4. Definitely would not have
- 98. (Don't know)
- 99. (Refused)

**[ASK D8 TO D11 IF AWARE OF REBATE (D1=1 or D2=2), RANDOMIZE D8 TO D11]**

D8. Without the BER rebate, what is the likelihood that you would have purchased the exact same model of premium lighting products? **[SINGLE RESPONSE]**

- 1. Definitely would have
- 2. Probably would have
- 3. Probably would not have
- 4. Definitely would not have
- 98. (Don't know)
- 99. (Refused)

D9. **[ASK IF C11=2]** If the rebate had not been offered, what is the likelihood that you would have kept your existing fixtures or lamps? **[SINGLE RESPONSE]**

1. Definitely would have
2. Probably would have
3. Probably would not have
4. Definitely would not have
98. (Don't know)
99. (Refused)

D10. **[ASK IF TOTAL MEASURE CATEGORY QTY>1]** Without the rebate, which of the following scenarios would have most likely occurred? **[SINGLE RESPONSE]**

You would have purchased...

1. ... exactly the same number of efficient lighting products
2. ...some, but not all of the efficient lighting products
3. You would not have purchased any efficient lighting products
98. (Don't know)
99. (Refused)

D11. **[ASK END USERS ONLY AND IF D7= 1 OR 2]** Without the program rebate, what is the likelihood that you would have postponed the purchase of the efficient lighting products by at least one year? **[SINGLE RESPONSE]**

1. Definitely would have
2. Probably would have
3. Probably would not have
4. Definitely would not have
98. (Don't know)
99. (Refused)

D12. How influential were the following four factors in your decision to purchase **<EFFICIENT PRODUCT>? [RANDOMIZE]**

| Factor (READ AND RANDOMIZE)                                                                                                             | Responses                                                                                                                                   |

## E. Cross-Influence

### ASK ALL - READ AND ROTATE (E1 + E2-E4) AND (E5 + E6-E8) SEQUENCES

E1. Before participating in the Business Energy Rebates program in **<APPLICATION DATE>**, had your company/organization at any time in the past already participated in the Business Energy Rebates program or any other Efficiency Nova Scotia programs? **[SINGLE RESPONSE]**

1. Yes, in Business Energy Rebates
2. Yes, in another program(s)
3. Yes, in both Business Energy Rebates and another program(s)
4. No **[GO TO E5]**
98. (Don't know) **[GO TO E5]**
99. (Refused) **[GO TO E5]**

For the following three statements, please indicate whether you agree or disagree.

- E2. **[IF E1=1, 2 OR 3]** Do you agree or disagree that your company/ organization's previous participation in an Efficiency Nova Scotia program was a major factor in the decision to purchase **<EFFICIENT PRODUCT>?** **[SINGLE RESPONSE]**
1. Agree
  2. Disagree
  98. (Don't know)
  99. (Refused)
- E3. **[ASK IF END USER A3=1 AND E1=1, 2 OR 3]** Do you agree or disagree that because of your company/ organization's previous participation in an Efficiency Nova Scotia program and what was learned by participating in that program, a company representative asked a contractor or a technical staff member to examine the energy efficiency options for your facility? **[SINGLE RESPONSE]**
1. Agree
  2. Disagree
  98. (Don't know)
  99. (Refused)
- E4. **[IF E1=1, 2 OR 3]** Do you agree or disagree that because of your company's previous participation in an Efficiency Nova Scotia program and what was learned by participating in that program, a company representative took into account the cost-effectiveness of energy-efficient **<EFFICIENT CATEGORY>** measures when evaluating different options for your facility? **[SINGLE RESPONSE]**
1. Agree
  2. Disagree
  98. (Don't know)
  99. (Refused)
- E5. **[ASK ALL]** Before participating in the Business Energy Rebates program, had you at any time in the past already seen Efficiency Nova Scotia promotional materials or communications advertising the benefits of energy efficiency? **[SINGLE RESPONSE]**
1. Yes
  2. No
  98. (Don't know) **[GO TO F1]**
  99. (Refused) **[GO TO F1]**

**[READ IF E5=1]** For the following statements, please indicate whether you agree or disagree.

- 
- E6. **[IF E5=1]** Do you agree or disagree that Efficiency Nova Scotia promotional materials or communications were a major factor in the company/organization's decision to purchase **<EFFICIENT PRODUCT>?****[SINGLE RESPONSE]**
1. Agree
  2. Disagree
  98. (Don't know)
  99. (Refused)
- E7. **[IF END USER A3=1 AND IF D5=1]** Do you agree or disagree that Efficiency Nova Scotia promotional materials or communications prompted a company representative to ask a contractor or a distributor about efficient lighting options for your organization?
1. Agree
  2. Disagree
  98. (Don't know)
  99. (Refused)
- E8. **[IF E5=1]** Do you agree or disagree that Efficiency Nova Scotia promotional materials or communications prompted a company representative to take into account the cost-effectiveness of **<EFFICIENT PRODUCT>** when evaluating different options for the facility? **[SINGLE RESPONSE]**
1. Agree
  2. Disagree
  98. (Don't know)
  99. (Refused)

## F. Market – LED Lighting

The next series of questions are about how the market for LED lighting is evolving in Nova Scotia

- F1. **[ASK IF A3 = 2]** Over the last year, have you made other lighting purchases for customers that received Efficiency Nova Scotia rebates at the distributor?
1. Yes
  2. No
  98. (Don't know)
  99. (Refused)
- F2. **[ASK IF A3=2 and F1=1 ]** Thinking about all the lighting projects this year where you purchased lighting for customers that received rebates, what proportion of the projects were for :
- New construction\_\_\_\_%      Replacement of existing fixtures or lamps\_\_\_\_% **[TOTAL MUST EQUAL 100%]**

F3. **[ASK IF Response to F2 Replacement of existing fixtures or lamps  $\neq$  0]** And, of those lighting projects that were for replacement of existing lamps or fixtures, what proportion of the existing lamps or fixtures were:

Working but at the end of their useful life \_\_\_\_%

Working and not close to the end of their useful life \_\_\_\_%

Broken \_\_\_\_%

**[TOTAL MUST EQUAL 100%]**

98. (Don't know)

99. (Refused)

F4. **[ASK IF CONTRACTOR (A3=2)]** Do you have customers who have been less likely or slower to adopt LED lighting than others?

1. Yes

2. No

98. (Don't know)

99. (Refused)

F5. **[ASK IF CONTRACTOR A3=2 AND F4=1]** Why do you think these customers are less likely or slower to adopt LED lighting? **[DO NOT READ—BUT CONFIRM WITH RESPONDENT THAT THE CATEGORY(IES) YOU MATCH TO THEIR RESPONSES ARE CORRECT- ACCEPT MULTIPLE RESPONSES]**

1. (Cost – less willing or able to pay for LED products)

2. (Lack of awareness of facility staff of LED products)

3. (Lack of knowledge of facility staff of LED products)

4. (Less technical applicability of LED products to their building or facility types)

96. (Other (SPECIFY: \_\_\_\_\_))

98. (Don't know)

99. (Refused)

F6. **[ASK IF CONTRACTOR A3=2]** In your experience, which facility or building types still have the most potential to adopt LED lighting? **[DO NOT READ—BUT CONFIRM WITH RESPONDENT THAT THE CATEGORY(IES) YOU MATCH TO THEIR RESPONSES ARE CORRECT- ACCEPT MULTIPLE RESPONSES]**

1. (Education)
2. (Food Sales (grocery))
3. (Food Service (restaurant))
4. (Health Care – Inpatient)
5. (Health Care – Outpatient)
6. (Lodging)
7. (Mercantile– Retail (Enclosed and Strip Malls))
8. (Mercantile – Retail (Other than Mall))
9. (Office)
10. (Public Assembly)
11. (Public Order and Safety)
12. (Religious Worship)
13. (Service)
14. (Warehouse / storage)
15. (Manufacturing)
16. (Building is vacant)
17. (Agriculture)
96. (Other (SPECIFY: \_\_\_\_\_))
98. (Don't know)
99. (Refused)

## G. Satisfaction

G1. **[ASK ALL]** On a scale of 1 to 10, where 1 is 'not at all satisfied' and 10 is 'completely satisfied,' how was your organization's experience with each of the following aspects of the Business Energy Rebates Program? If your organization did not have experience with one of these aspects please tell me. **[DO NOT RANDOMIZE] [97 = NOT APPLICABLE, 98 = DON'T KNOW/DON'T RECALL, 99 = REFUSED]**

- a) Interaction and communication with distributors
- b) Rebate amounts
- c) Eligible products

- G2. Why were you not more satisfied with the **[READ STATEMENTS IN ORDER AS APPLICABLE]**  
**[DO NOT READ PRE-CODES. PROBE FOR SPECIFIC REASON. ACCEPT MULTIPLE RESPONSES. repeat entire question text for G2A AND G2B]**
- a. **[ASK G1A<8]** Interaction and communication with distributors
1. (Lack of communication/availability with distributors)
  2. (Less knowledgeable about the program)
  3. (Took too long/Communication was slow)
  96. (Other: \_\_\_\_\_)
  98. (Don't know)
  99. (Refused)
- b. **[ASK IF G1B<8]** Rebate amounts
1. (Rebate is too small/Expected higher rebate)
  2. (Cost of measures was expensive)
  96. (Other: \_\_\_\_\_)
  98. (Don't know)
  99. (Refused)
- c. **[ASK IF G1C<8]** Were there other types of efficient equipment or services you would have liked to see Efficiency Nova Scotia provide rebates for? **[OPEN-END RESPONSE]**
98. (Don't know)
- G3. **[ASK ALL]** Using a scale from 1 to 10 where 1 is “not at all satisfied” and 10 is “completely satisfied” how would you rate your satisfaction with the Business Energy Rebates – Instant Rebates program overall? **[RECORD NUMBER, 98=DON'T KNOW, 99 REFUSED]** **[DO NOT ACCEPT A RANGE]**
- G4. **[IF G3<8]** What was the most important reason you were not more satisfied with the Instant Rebates program overall? **[DO NOT READ. PROBE FOR SPECIFIC REASON. ACCEPT MULTIPLE RESPONSES]** Probe: Any other reasons? **[RECORD FIRST AND SUBSEQUENT MENTIONS SEPARATELY]**
1. (Too expensive)
  2. (I don't like the products rebated)
  3. (Rebate/incentive is too small)
  96. (Other (SPECIFY: \_\_\_\_\_)
  98. (Don't know)
  99. (Refused)

G5. Do you have any suggestions on how to improve the Business Energy Rebates - Instant Rebates program?

Probe: Anything else? **[DO NOT READ. ACCEPT MULTIPLE KEEPING CODE 98 AND 99 EXCLUSIVE]**

1. Improve communication
2. Simplify the program/Less paperwork
3. Better marketing/awareness
4. Increase rebates
5. Offer more measures eligible for rebates
6. No recommendations
96. (Other (SPECIFY: \_\_\_\_\_))
98. (Don't know)
99. (Refused)

**END.** Those are all the questions I have for you. I thank you very much for your time and cooperation and have a nice day!

## APPENDIX II

### BER Instant Rebates Participant Survey Results

A3. Did you purchase these products for your own organization, or are you a company purchasing products for a customer or project outside of your organization?

| Purchase for Contractor or End User                                                   | 2018 | 2019 | 2020 | 2021 | 2022 | 2024 |

## Introduction

### A. INTRODUCTION A – Business with a contact name

Could I speak with <INSERT NAME>?

1. Yes [CONTINUE]
2. No [SAY “PERHAPS YOU CAN HELP ME ANYWAY.” GO TO INTRODUCTION B]

Hello, I am with Narrative Research, and we are conducting an evaluation of energy efficiency services provided by Efficiency Nova Scotia. We have a few questions about your recent experience with Efficiency Nova Scotia’s Business Energy Rebates Program through which you or your organization recently purchased rebated <EFFICIENT PRODUCT> at a participating distributor. More precisely, we are referring to the purchase of <QUANTITY SOLD> <PRODUCT BRAND> <EFFICIENT PRODUCT> made in <MONTH OF PURCHASE> through <DISTRIBUTOR>, for which you received a rebate of <REBATE AMOUNT>.

- A1. Are you the person in your organization who is most knowledgeable about the decision to purchase these <EFFICIENT PRODUCT> from <DISTRIBUTOR> in 2024?
1. Yes [GO TO A3]
  2. No [GO TO A2]
- A2. Is there someone else in your organization who would know about the decision to purchase these <EFFICIENT PRODUCT>? [PROBE IF UNSURE: This person may be an engineer, equipment contractor, or utility account manager].
1. Yes [ASK for name: \_\_\_\_\_ and telephone #: \_\_\_\_\_] [ASK TO SPEAK TO THAT PERSON AND RESTART AT INTRODUCTION. IF OTHER PERSON IS UNAVAILABLE, THANK, TERMINATE, RECORD DATA AND SCHEDULE INTERVIEW WITH BEST CONTACT]
  2. No [THANK & TERMINATE AND RECORD DATA]
- A3. Did you purchase these products for your own organization, or are you a company purchasing products for a customer or project outside of your organization? [SINGLE RESPONSE]
1. I purchased the products for my organization
  2. I purchased the products for a customer or project outside of my organization/I am a contractor
  3. Other, please specify [IF BOTH, SELECT OPTION 1]
  98. Don’t know
  99. Refused

- A4. To help Efficiency Nova Scotia improve the Business Energy Rebates program, would you have a few minutes to answer questions about your organization's participation in the program?

**(IF NEEDED:** The survey will take about 10 minutes to complete. )

**(IF NEEDED:** You may have recently been contacted by Narrative Research or by an Efficiency Nova Scotia representative about your experience with the service. This survey is different as it focuses on other aspects of your participation in the service.)

1. Yes **[CONTINUE]**
2. No **[ASK "CAN WE SCHEDULE A MORE CONVENIENT TIME FOR YOU TO CONDUCT THIS SURVEY?"] [IF NO, THANK, TERMINATE AND RECORD DATA] [IF YES, SCHEDULE CALLBACK]**

## **B. INTRODUCTION B – Business with no contact name**

Hello, I am with Narrative Research, and we are conducting an evaluation of energy efficiency services provided by Efficiency Nova Scotia. We have a few questions about your recent experience with Efficiency Nova Scotia's Business Energy Rebates Program through which you or your organization recently purchased rebated **<EFFICIENT PRODUCT>** at a participating distributor. More precisely, we are referring to the purchase of **<QUANTITY SOLD> <PRODUCT BRAND> <EFFICIENT PRODUCT>** made in **<MONTH OF PURCHASE>** through **<DISTRIBUTOR>**, for which you received a rebate of **<REBATE AMOUNT>**.

- B1. Could you help us identify the person who is most knowledgeable about the decision to purchase these products? **[PROBE IF UNSURE:** This person may be an engineer, equipment contractor, or utility account manager].
1. Yes, the person is **[RECORD NAME AND TELEPHONE NUMBER AND ASK TO SPEAK TO THIS PERSON – GO BACK TO INTRO A]**
  2. Yes, but the person is unavailable **[RECORD NAME AND TELEPHONE NUMBER. THANK AND TERMINATE; SCHEDULE CALL BACK TO SPEAK TO THAT PERSON]**
  3. No **[THANK, TERMINATE AND RECORD DATA]**

## **C. Participation and Decision to Purchase**

- C1. **[ASK IF CONTRACTOR A3=2]** Who usually makes the decision to buy **<EFFICIENT PRODUCT>** rather than standard **<STANDARD PRODUCT>**? Is it... **[READ CODE 1-2 AND 96. SINGLE RESPONSE]**.
1. You or someone else in your organization
  2. Your customer
  96. Someone else (SPECIFY: \_\_\_\_\_)
  98. (Don't know)

C2. **[ASK IF END-USER A3=1 OR C1=1]** Can you describe the main activity of your organization? **[DO NOT READ BUT CONFIRM WITH RESPONDENT THAT THE CATEGORY YOU CHOOSE IS CORRECT]**

1. (Agriculture)
2. (Banking)
3. (Education)
4. (Health Care)
5. (Hospitality)
6. (Manufacturing/Industrial)
7. (Office/Commercial)
8. (Public Service)
9. (Residential)
10. (Restaurant/Bar)
11. (Retail)
12. (Technology/Science)
13. (Warehouse / storage)
96. (Other (SPECIFY: \_\_\_\_\_))
98. (Don't know)
99. (Refused)

C3. **[ASK IF C1=2]** Before making the decision to purchase <EFFICIENT PRODUCT>, do customers usually ask for your advice? **[SINGLE RESPONSE]**

1. Yes **[GO TO C7]**
2. No **[GO TO C9]**
98. Don't Know **[GO TO C9]**
99. Refused **[GO TO C9]**

C4. **[ASK IF A3=1, C1=1 OR C3=1]** Now, I would like to understand your decision-making process for selecting LED lighting. Did you consider any alternatives to <EFFICIENT PRODUCT> before making your purchase decision? **[SINGLE RESPONSE]**

1. Yes
2. No
98. (Don't know)
99. (Refused)

- C5. **[ASK IF A3=1, C1=1 OR C3=1 AND <LINEAR LAMP>]** What lighting alternatives did you consider? **[DO NOT READ, ACCEPT MULTIPLE RESPONSES]**
1. Standard LED
  2. Incandescent lighting
  3. Fluorescent lighting
  4. Halogen lighting
  5. Other lighting (specify)
  98. (Don't know)
  99. (Refused)
- C6. **[ASK IF A3=1, C1=1 OR C3=1 AND <LINEAR OR OUTDOOR FIXTURE>]** What alternatives to LED fixtures did you consider? **[DO NOT READ, SINGLE RESPONSE]**
1. Keep existing fluorescent fixture
  2. Change for another fluorescent fixture
  3. Other (specify)
  98. (Don't know)
  99. (Refused)
- C7. **[ASK IF A3=1, C1=1 OR C3=1]** What was the SINGLE most important reason you purchased **<EFFICIENT PRODUCT>** rather than standard **<STANDARD PRODUCT>**? **[DO NOT READ. SINGLE RESPONSE.]**
1. Availability of other alternatives
  2. Energy efficiency
  3. Cost savings
  4. Lifespan
  5. Efficiency Nova Scotia program incentives
  6. Environmental cause
  7. Contractor influence
  8. Distributor influence
  96. (Other (SPECIFY: \_\_\_\_\_))
  98. (Don't know)
  99. (Refused)

- C8. **[ASK IF A3=1, C1=1 OR C3=1; DO NOT ASK IF 98 OR 99 IN C4]** What was the SECOND most important reason you purchased <EFFICIENT PRODUCT> rather than standard <STANDARD PRODUCT>? **[DO NOT READ. SINGLE RESPONSE.]**
1. Availability of other alternatives
  2. Energy efficiency
  3. Cost savings
  4. Lifespan
  5. Efficiency Nova Scotia program incentives
  6. Environmental cause
  7. Contractor influence
  8. Distributor influence
  96. (Other (SPECIFY: \_\_\_\_\_))
  97. No other reason
  98. (Don't know)
- C9. **[ASK ALL]** Did your distributor recommend <EFFICIENT PRODUCT> to you? **[SINGLE RESPONSE]**
1. Yes
  2. No
  98. (Don't know)
  99. (Refused)
- C10. For what type of project did you purchase the <EFFICIENT PRODUCT>? Was it for a... **[READ. SINGLE RESPONSE]**
1. New construction
  2. Replacement of existing fixtures or lamps
  98. (Don't know)
  99. (Refused)
- C11. **[ASK IF C10=2]** In what state were the existing fixtures or lamps when you decided to purchase the <EFFICIENT PRODUCT>? Were they... **[READ. SINGLE RESPONSE]**
1. Working but at the end of their useful life
  2. Working and not close to the end of their useful life
  3. Broken
  4. **[DO NOT READ]** (Some were working, some were not working)
  96. **[DO NOT READ]** (Other (SPECIFY: \_\_\_\_\_))
  98. (Don't know)
  99. (Refused)

## D. Free-Ridership

- D1. **[ASK ALL]** Were you aware that you received a rebate when purchasing these <EFFICIENT PRODUCT>? **[SINGLE RESPONSE]**
1. Yes
  2. No
  98. (Don't know)
- D2. **[ASK IF D1=2 OR 98]** Have I understood correctly that you were not aware that a rebate would be given on the product's total cost when you purchased these items? **[DO NOT READ. SINGLE RESPONSE]**
1. Yes, correct (unaware of the rebate)
  2. No, incorrect (aware of the rebate)
  98. Don't know
  99. Refused
- D3. **[ASK IF D1=1 OR D2=2]** Were you aware that the rebate was offered by Efficiency Nova Scotia? **[SINGLE RESPONSE]**
1. Yes
  2. No
  98. Don't know
- D4. **[ASK IF END-USER A3=1 AND D3=1]** How did you first become aware of the rebates available from Efficiency Nova Scotia's Business Energy Rebates Program? **[DO NOT READ. SINGLE RESPONSE]**
1. Through my contractor
  2. Through my distributor
  3. Efficiency Nova Scotia staff contacted me about the program
  4. Efficiency Nova Scotia website
  5. Efficiency Nova Scotia promotion
  6. Past experience with another Efficiency Nova Scotia program
  7. Word of mouth from other organizations/businesses/Friends/Family
  8. Online - general
  96. Other, please specify
  98. Don't know
  99. Refused

- D5. **[ASK ALL]** Had you *already* decided to purchase these **<EFFICIENT PRODUCT>** *before* talking to a distributor? **[SINGLE RESPONSE]**
1. Yes
  2. No
  98. (Don't know)
  99. (Refused)
- D6. **[ASK IF AWARE (D1=1 or D2=2)]** Had you *already* decided to purchase these **<EFFICIENT PRODUCT>** *before* knowing that these efficient products were rebated? **[SINGLE RESPONSE]**
1. Yes
  2. No
  98. (Don't know)
  99. (Refused)
- D7. **[ASK ALL]** Efficiency Nova Scotia offered a rebate for the purchase of efficient lighting products. If your organization had not received the rebate and the cost of **<EFFICIENT PRODUCT>** had been about **<REBATE AVERAGE VALUE BY CATEGORY>** higher per unit, what is the likelihood you would have paid the full cost of the **<EFFICIENT PRODUCT>?** **[SINGLE RESPONSE]**
1. Definitely would have
  2. Probably would have
  3. Probably would not have
  4. Definitely would not have
  98. (Don't know)
  99. (Refused)

**[ASK D8 TO D11 IF AWARE OF REBATE (D1=1 or D2=2), RANDOMIZE D8 TO D11]**

- D8. Without the BER rebate, what is the likelihood that you would have purchased the exact same model of premium lighting products? **[SINGLE RESPONSE]**
1. Definitely would have
  2. Probably would have
  3. Probably would not have
  4. Definitely would not have
  98. (Don't know)
  99. (Refused)

D9. **[ASK IF C11=2]** If the rebate had not been offered, what is the likelihood that you would have kept your existing fixtures or lamps? **[SINGLE RESPONSE]**

1. Definitely would have
2. Probably would have
3. Probably would not have
4. Definitely would not have
98. (Don't know)
99. (Refused)

D10. **[ASK IF TOTAL MEASURE CATEGORY QTY>1]** Without the rebate, which of the following scenarios would have most likely occurred? **[SINGLE RESPONSE]**

You would have purchased...

1. ... exactly the same number of efficient lighting products
2. ...some, but not all of the efficient lighting products
3. You would not have purchased any efficient lighting products
98. (Don't know)
99. (Refused)

D11. **[ASK END USERS ONLY AND IF D7= 1 OR 2]** Without the program rebate, what is the likelihood that you would have postponed the purchase of the efficient lighting products by at least one year? **[SINGLE RESPONSE]**

1. Definitely would have
2. Probably would have
3. Probably would not have
4. Definitely would not have
98. (Don't know)
99. (Refused)

D12. How influential were the following four factors in your decision to purchase **<EFFICIENT PRODUCT>? [RANDOMIZE]**

| Factor (READ AND RANDOMIZE)                                                                                                             | Responses                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| a. <b>[ASK IF D1=1 OR D2=2]</b> The program rebate                                                                                      | 1. Very influential<br>2. Somewhat influential<br>3. Not very influential<br>4. Not at all influential<br>98. (Don't know)<br>99. (Refused) |
| b. <b>[ASK IF D3=1]</b> Information received from an Efficiency Nova Scotia program representative on high-efficiency lighting products | 1. Very influential<br>2. Somewhat influential<br>3. Not very influential<br>4. Not at all influential<br>98. (Don't know)<br>99. (Refused) |
| c. <b>[ASK ALL]</b> Information received from a distributor on high-efficiency lighting products                                        | 1. Very influential<br>2. Somewhat influential<br>3. Not very influential<br>4. Not at all influential<br>98. (Don't know)<br>99. (Refused) |
| d. <b>[ASK ALL]</b> Prevalence of LED products among products that met your lighting requirements                                       | 1. Very influential<br>2. Somewhat influential<br>3. Not very influential<br>4. Not at all influential<br>98. (Don't know)<br>99. (Refused) |

## E. Cross-Influence

### ASK ALL - READ AND ROTATE (E1 + E2-E4) AND (E5 + E6-E8) SEQUENCES

E1. Before participating in the Business Energy Rebates program in **<APPLICATION DATE>**, had your company/organization at any time in the past already participated in the Business Energy Rebates program or any other Efficiency Nova Scotia programs? **[SINGLE RESPONSE]**

1. Yes, in Business Energy Rebates
2. Yes, in another program(s)
3. Yes, in both Business Energy Rebates and another program(s)
4. No **[GO TO E5]**
98. (Don't know) **[GO TO E5]**
99. (Refused) **[GO TO E5]**

For the following three statements, please indicate whether you agree or disagree.

- E2. **[IF E1=1, 2 OR 3]** Do you agree or disagree that your company/ organization's previous participation in an Efficiency Nova Scotia program was a major factor in the decision to purchase **<EFFICIENT PRODUCT>?** **[SINGLE RESPONSE]**
1. Agree
  2. Disagree
  98. (Don't know)
  99. (Refused)
- E3. **[ASK IF END USER A3=1 AND E1=1, 2 OR 3]** Do you agree or disagree that because of your company/ organization's previous participation in an Efficiency Nova Scotia program and what was learned by participating in that program, a company representative asked a contractor or a technical staff member to examine the energy efficiency options for your facility? **[SINGLE RESPONSE]**
1. Agree
  2. Disagree
  98. (Don't know)
  99. (Refused)
- E4. **[IF E1=1, 2 OR 3]** Do you agree or disagree that because of your company's previous participation in an Efficiency Nova Scotia program and what was learned by participating in that program, a company representative took into account the cost-effectiveness of energy-efficient **<EFFICIENT CATEGORY>** measures when evaluating different options for your facility? **[SINGLE RESPONSE]**
1. Agree
  2. Disagree
  98. (Don't know)
  99. (Refused)
- E5. **[ASK ALL]** Before participating in the Business Energy Rebates program, had you at any time in the past already seen Efficiency Nova Scotia promotional materials or communications advertising the benefits of energy efficiency? **[SINGLE RESPONSE]**
1. Yes
  2. No
  98. (Don't know) **[GO TO F1]**
  99. (Refused) **[GO TO F1]**

**[READ IF E5=1]** For the following statements, please indicate whether you agree or disagree.

- 
- E6. **[IF E5=1]** Do you agree or disagree that Efficiency Nova Scotia promotional materials or communications were a major factor in the company/organization's decision to purchase <EFFICIENT PRODUCT>? **[SINGLE RESPONSE]**
1. Agree
  2. Disagree
  98. (Don't know)
  99. (Refused)
- E7. **[IF END USER A3=1 AND IF D5=1]** Do you agree or disagree that Efficiency Nova Scotia promotional materials or communications prompted a company representative to ask a contractor or a distributor about efficient lighting options for your organization?
1. Agree
  2. Disagree
  98. (Don't know)
  99. (Refused)
- E8. **[IF E5=1]** Do you agree or disagree that Efficiency Nova Scotia promotional materials or communications prompted a company representative to take into account the cost-effectiveness of <EFFICIENT PRODUCT> when evaluating different options for the facility? **[SINGLE RESPONSE]**
1. Agree
  2. Disagree
  98. (Don't know)
  99. (Refused)

## F. Market – LED Lighting

The next series of questions are about how the market for LED lighting is evolving in Nova Scotia

- F1. **[ASK IF A3 = 2]** Over the last year, have you made other lighting purchases for customers that received Efficiency Nova Scotia rebates at the distributor?
1. Yes
  2. No
  98. (Don't know)
  99. (Refused)
- F2. **[ASK IF A3=2 and F1=1 ]** Thinking about all the lighting projects this year where you purchased lighting for customers that received rebates, what proportion of the projects were for :
- New construction \_\_\_\_\_%      Replacement of existing fixtures or lamps \_\_\_\_\_% **[TOTAL MUST EQUAL 100%]**

F3. **[ASK IF Response to F2 Replacement of existing fixtures or lamps  $\neq$  0]** And, of those lighting projects that were for replacement of existing lamps or fixtures, what proportion of the existing lamps or fixtures were:

Working but at the end of their useful life \_\_\_\_%

Working and not close to the end of their useful life \_\_\_\_%

Broken \_\_\_\_%

**[TOTAL MUST EQUAL 100%]**

98. (Don't know)

99. (Refused)

F4. **[ASK IF CONTRACTOR (A3=2)]** Do you have customers who have been less likely or slower to adopt LED lighting than others?

1. Yes

2. No

98. (Don't know)

99. (Refused)

F5. **[ASK IF CONTRACTOR A3=2 AND F4=1]** Why do you think these customers are less likely or slower to adopt LED lighting? **[DO NOT READ—BUT CONFIRM WITH RESPONDENT THAT THE CATEGORY(IES) YOU MATCH TO THEIR RESPONSES ARE CORRECT- ACCEPT MULTIPLE RESPONSES]**

1. (Cost – less willing or able to pay for LED products)

2. (Lack of awareness of facility staff of LED products)

3. (Lack of knowledge of facility staff of LED products)

4. (Less technical applicability of LED products to their building or facility types)

96. (Other (SPECIFY: \_\_\_\_\_))

98. (Don't know)

99. (Refused)

F6. **[ASK IF CONTRACTOR A3=2]** In your experience, which facility or building types still have the most potential to adopt LED lighting? **[DO NOT READ—BUT CONFIRM WITH RESPONDENT THAT THE CATEGORY(IES) YOU MATCH TO THEIR RESPONSES ARE CORRECT- ACCEPT MULTIPLE RESPONSES]**

1. (Education)
2. (Food Sales (grocery))
3. (Food Service (restaurant))
4. (Health Care – Inpatient)
5. (Health Care – Outpatient)
6. (Lodging)
7. (Mercantile– Retail (Enclosed and Strip Malls))
8. (Mercantile – Retail (Other than Mall))
9. (Office)
10. (Public Assembly)
11. (Public Order and Safety)
12. (Religious Worship)
13. (Service)
14. (Warehouse / storage)
15. (Manufacturing)
16. (Building is vacant)
17. (Agriculture)
96. (Other (SPECIFY: \_\_\_\_\_))
98. (Don't know)
99. (Refused)

## G. Satisfaction

G1. **[ASK ALL]** On a scale of 1 to 10, where 1 is 'not at all satisfied' and 10 is 'completely satisfied,' how was your organization's experience with each of the following aspects of the Business Energy Rebates Program? If your organization did not have experience with one of these aspects please tell me. **[DO NOT RANDOMIZE] [97 = NOT APPLICABLE, 98 = DON'T KNOW/DON'T RECALL, 99 = REFUSED]**

- a) Interaction and communication with distributors
- b) Rebate amounts
- c) Eligible products

- G2. Why were you not more satisfied with the **[READ STATEMENTS IN ORDER AS APPLICABLE]**  
**[DO NOT READ PRE-CODES. PROBE FOR SPECIFIC REASON. ACCEPT MULTIPLE RESPONSES. repeat entire question text for G2A AND G2B]**
- a. **[ASK G1A<8]** Interaction and communication with distributors
1. (Lack of communication/availability with distributors)
  2. (Less knowledgeable about the program)
  3. (Took too long/Communication was slow)
  96. (Other: \_\_\_\_\_)
  98. (Don't know)
  99. (Refused)
- b. **[ASK IF G1B<8]** Rebate amounts
1. (Rebate is too small/Expected higher rebate)
  2. (Cost of measures was expensive)
  96. (Other: \_\_\_\_\_)
  98. (Don't know)
  99. (Refused)
- c. **[ASK IF G1C<8]** Were there other types of efficient equipment or services you would have liked to see Efficiency Nova Scotia provide rebates for? **[OPEN-END RESPONSE]**
98. (Don't know)
- G3. **[ASK ALL]** Using a scale from 1 to 10 where 1 is “not at all satisfied” and 10 is “completely satisfied” how would you rate your satisfaction with the Business Energy Rebates – Instant Rebates program overall? **[RECORD NUMBER, 98=DON'T KNOW, 99 REFUSED]** **[DO NOT ACCEPT A RANGE]**
- G4. **[IF G3<8]** What was the most important reason you were not more satisfied with the Instant Rebates program overall? **[DO NOT READ. PROBE FOR SPECIFIC REASON. ACCEPT MULTIPLE RESPONSES]** Probe: Any other reasons? **[RECORD FIRST AND SUBSEQUENT MENTIONS SEPARATELY]**
1. (Too expensive)
  2. (I don't like the products rebated)
  3. (Rebate/incentive is too small)
  96. (Other (SPECIFY: \_\_\_\_\_)
  98. (Don't know)
  99. (Refused)

G5. Do you have any suggestions on how to improve the Business Energy Rebates - Instant Rebates program?

Probe: Anything else? **[DO NOT READ. ACCEPT MULTIPLE KEEPING CODE 98 AND 99 EXCLUSIVE]**

- 4. Improve communication
- 5. Simplify the program/Less paperwork
- 6. Better marketing/awareness
- 7. Increase rebates
- 8. Offer more measures eligible for rebates
- 9. No recommendations
- 96. (Other (SPECIFY: \_\_\_\_\_))
- 98. (Don't know)
- 99. (Refused)

**END.** Those are all the questions I have for you. I thank you very much for your time and cooperation and have a nice day!

## APPENDIX IV

### BER Application Rebates Tracking Sheet Audit

This appendix presents the main results of the tracking sheet audit performed by the Evaluator, which was aimed at:

- › Verifying that all data fields required for the evaluation were included and filled out in the tracking sheet submitted by E1
- › Ensuring that tracked results were accurate by:
  - › Verifying that the parameters used to calculate service results (gross and net electrical energy and peak demand savings at the generator) were consistent with previous evaluation results
  - › Validating that all calculation steps were performed consistently

Table 1 presents the corrected tracked savings resulting from all changes made by the Evaluator.

**Table 1: 2024 Application Rebates Corrected Tracked Savings**

| Service Result                             | Value Tracked by E1 |      | Corrected Tracked Value |      | Relative Difference |
|--------------------------------------------|---------------------|------|-------------------------|------|---------------------|
|                                            | Value               | Unit | Value                   | Unit | Value               |
| <b>BER Application Rebates</b>             |                     |      |                         |      |                     |
| Gross Energy Savings at the Generator      | 15.582              | GWh  | 15.582                  | GWh  | 0.00%               |
| Gross Peak Demand Savings at the Generator | 1.902               | MW   | 1.902                   | MW   | 0.00%               |
| Net Energy Savings at the Generator        | 11.530              | GWh  | 11.530                  | GWh  | 0.00%               |
| Net Peak Demand Savings at the Generator   | 1.407               | MW   | 1.407                   | MW   | 0.00%               |

## APPENDIX V

### BER Instant Rebates Tracking Sheet Audit

This appendix presents the main results of the tracking sheet audit performed by the Evaluator, which was aimed at:

- › Verifying that all data fields required for the evaluation were included and filled out in the tracking sheet submitted by E1
- › Ensuring that tracked results were accurate by:
  - › Verifying that the parameters used to calculate service results (gross and net energy and peak demand savings at the generator) were consistent with previous evaluation results
  - › Validating that all calculation steps were performed consistently

Table 1 and Table 2 below present the corrected tracked savings resulting from all changes made by the Evaluator.

**Table 1: 2024 Instant Rebates Corrected Tracked Savings - Lighting**

| Service Results                            | Value Tracked by E1 |      | Corrected Tracked Value |      | Relative Difference |
|--------------------------------------------|---------------------|------|-------------------------|------|---------------------|
|                                            | Value               | Unit | Value                   | Unit | Value               |
| <b>Instant Rebates - Lighting</b>          |                     |      |                         |      |                     |
| Gross Energy Savings at the Generator      | 31.777              | GWh  | 31.796                  | GWh  | 0.06%               |
| Gross Peak Demand Savings at the Generator | 4.665               | MW   | 4.960                   | MW   | 6.34%               |
| Net Energy Savings at the Generator        | 26.581              | GWh  | 26.613                  | GWh  | 0.12%               |
| Net Peak Demand Savings at the Generator   | 3.850               | MW   | 4.134                   | MW   | 7.38%               |

Tracked gross and net electrical energy savings at the generator were almost identical with less than 1% difference with the corrected values. This was due to occupancy sensor entries having inconsistent unitary energy savings and, to a lesser extent, a few entries having inconsistent interactive effects factors for energy savings and wattage baselines.

The differences between tracked and corrected peak demand savings at the generator were larger for both the gross and net values with differences of 6% and 7% respectively. These were due to many entries having either inconsistent interactive effects factors for peak demand savings, peak coincidence factors, unitary demand savings values, or net-to-gross ratios.

**Table 2: 2024 Instant Rebates Corrected Tracked Savings - Pumping**

| Program Component Results                  | Value Tracked by E1 |      | Corrected Tracked Value |      | Relative Difference |
|--------------------------------------------|---------------------|------|-------------------------|------|---------------------|
|                                            | Value               | Unit | Value                   | Unit | Value               |
| <b>Instant Rebates - Pumping</b>           |                     |      |                         |      |                     |
| Gross Energy Savings at the Generator      | 0.455               | GWh  | 0.455                   | GWh  | -0.09%              |
| Gross Peak Demand Savings at the Generator | 0.071               | MW   | 0.071                   | MW   | -0.09%              |
| Net Energy Savings at the Generator        | 0.455               | GWh  | 0.455                   | GWh  | -0.09%              |
| Net Peak Demand Savings at the Generator   | 0.071               | MW   | 0.071                   | MW   | -0.09%              |

Tracked and corrected electrical energy and peak demand savings at the generator were slightly different for both gross and net results.

The differences between tracked and corrected values at the generator are due to inconsistent line loss factors for both electrical energy and demand savings.

## APPENDIX VI

### BER Instant Rebates Algorithm for Free-Ridership Calculations

---

Table 1 and Table 2 below present the algorithms<sup>1</sup> used to calculate the free-ridership levels for Instant Rebates measures. The algorithms are based on participant survey questions designed to assess program influence on variables such as planning, quantity, efficiency, timing, cost, and distributor influence on participant decision-making. The algorithms also incorporate distributor interview questions designed to assess the influence of the program on distributors' sales strategies. Distributor influence levels were obtained for each distributor and then applied to the free-ridership results of participants who purchased products at the given distributor.

---

<sup>1</sup> As part of the 2024 evaluation, the Evaluator conducted a Net-to-gross Review and all algorithms, including BER-IR, were updated.

## BER Instant Rebates – Distributor Interview

**Table 1: Instant Rebates Distributor Influence Level Algorithm**

| 2022 Algorithm |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                 |                  | 2024 Algorithm                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                |                       |

## APPENDIX VII

### BER Instant Rebates Jurisdictional Scan

To further supplement the market evaluation findings, the Evaluator conducted a jurisdictional scan to investigate similar programs to BER-IR. **The Evaluator found very few instant discount programs targeted at the BNI sector.** BC Hydro, Efficiency Manitoba, NB Power, Efficiency Vermont, Efficiency Maine, and PG&E do not have an instant discount program. Con Edison's program at first glance looks like an instant program, although it is more like BER-AR, requiring a contractor to replace inefficient lighting. As presented in table below, the Evaluator found only one instant discount program (the IESO program) that incents lighting. The IESO program requires that incented measures replace less efficient lighting, similarly to BER-AR.

| Jurisdiction - Program                               | Measures                                                                                                         | Baseline Information                                                                                               | Notes                                                                                                                                                                                                                                                                                                                                                       |

## APPENDIX VIII

### BER 2024 Recommendations

This appendix summarizes all the recommendations made by the Evaluator as part of the 2024 BER evaluation.

| Section           | Recommendations                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Executive Summary | Recommendation #1: Undertake additional research to further validate the market evaluation results to establish, no later than Q3, when the LED baseline for BER-IR LED fixtures should take effect. Research should focus on the potential risk of the fixture market rebounding from reducing or removing the Instant incentives in the Nova Scotia market.                                |
| Executive Summary | Recommendation #2: Review the eligibility criteria for LED lighting in new construction projects in BER-AR given evidence that LEDs are the baseline for this market.                                                                                                                                                                                                                        |
| Executive Summary | Recommendation #3: In line with Recommendation #1, research should also investigate the efficiency level of an LED baseline for LED fixtures.                                                                                                                                                                                                                                                |
| Executive Summary | Recommendation #4: The current non-LED baseline for lamps should be maintained for BER-IR and reassessed in 2026. Given trends, E1 should plan for a baseline change starting in 2027.                                                                                                                                                                                                       |
| Executive Summary | Recommendation #5: Plan for a shift in the product offer for LED fixtures from BER-IR to BER-AR to capture remaining retrofit opportunities once LED baseline is adopted for BER-IR.                                                                                                                                                                                                         |
| Executive Summary | Recommendation #6: Focus efforts on BER-AR to target market laggards for early replacement retrofits of their lighting.                                                                                                                                                                                                                                                                      |
| Executive Summary | Recommendation #7: A LED baseline should also be applied to the EUL of LED fixtures rebated through BER-AR and SBES to reflect the fact that existing fixtures would have been replaced with LED fixtures at the end of their life. The baseline should consider the proportion of projects targeted for early replacement versus replace on burn-out as well as an estimated remaining EUL. |
| Executive Summary | Recommendation #8: Analyze opportunities for increasing interest around controlled lighting products                                                                                                                                                                                                                                                                                         |
| Executive Summary | Recommendation #9: Ensure that multi-wattage products are identified in the tracking sheet. Update applications for BER-AR and SBES to identify multi-wattage products and confirm the wattage being used. Select the middle wattage (i.e. not the lowest or highest) as the tracked wattage when information is not available from the participant.                                         |

## DEFINITIONS

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Accuracy</b>                           | Reflects the proximity of measurements to the true value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Adjustment ratio</b>                   | The ratio of evaluated results to tracked results. This ratio expresses the adjustment made to tracked savings or other tracked values such as effective useful life values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Available Demand Response Capacity</b> | The capacity that is available to Nova Scotia Power (NS Power) to reduce system peak demand. This capacity is calculated based on the first two hours of all events called between December and February, excluding weekends and holidays. If an event is shorter than two hours, only the first hour is used to measure available demand response (DR) capacity. Available DR capacity is evaluated on a per-participant basis based on the average demand reduction observed for each event in which the participant was scheduled to participate. E1's total available DR capacity is the sum of each participant's available DR capacity. |
| <b>Baseline</b>                           | To determine gross savings, a baseline (or base case) is established, providing detailed information about the reference (e.g. pre-existing or standard) measure or equipment chosen to be compared with the efficient measure or equipment. For the reference measure or equipment, the baseline may include such information as the hours of operation, wattage, and base consumption.                                                                                                                                                                                                                                                      |
| <b>Bias</b>                               | Systematic deviations of measurements from the true value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Billing calibration</b>                | An activity that consists of adjusting the expected energy savings based on the relative difference between the results of energy simulations and the actual energy consumption of a building or system.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Confidence interval</b>                | The estimated range of values that is likely to include unknown population parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Demand response</b>                    | Demand response measures generate savings in the form of available capacity or a load reduction in response to events called by the electric utility (NS Power) to reduce the load at strategic moments. These events can be called at any time and for any duration, although they are usually called for one to four hours during peak periods.                                                                                                                                                                                                                                                                                             |
| <b>Displaced wattage</b>                  | The displaced wattage is defined as the difference between the wattage values of the baseline equipment or product and that of the efficient equipment or product.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>EnerGuide rating</b>                   | An EnerGuide (official brand of Natural Resources Canada) rating is a standard measure of home energy performance. It is a measure of the efficiency of the building only and does not take into account occupant behaviour. It shows how energy efficient a home is through modelled home heat losses based on several factors including building envelope characteristics, heated volume, heating systems, and air leakage.                                                                                                                                                                                                                 |
| <b>Effective useful life</b>              | The period a measure is expected to be in service and provide both electrical energy and peak demand savings. This value combines equipment life and measure persistence, which includes factors such as business turnover or early retirement.                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Equipment life</b>                     | The number of years installed equipment will operate before it fails.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                                         |                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Equivalent CO2</b>                   | A unit of measurement indicating the amount of carbon dioxide to which various kinds of emitted greenhouse gases are equivalent in terms of warming effects. In this report, gas global warming potential is estimated over a timescale of 100 years.                                                                           |
| <b>Equivalent effective useful life</b> | The number of years by which the first-year savings estimate is multiplied to obtain lifetime energy savings. This value takes into account variations in annual electrical energy savings throughout the effective useful life due to increased baselines.                                                                     |
| <b>Evaluated savings</b>                | Gross and net electrical energy or peak demand savings calculated by the Evaluator using the parameters (unitary savings values, installation rates, interactive effects, net-to-gross ratios, etc.) validated or measured during the evaluation process. Unless otherwise specified, evaluated savings are first-year savings. |
| <b>Evaluation plan</b>                  | The evaluation plan summarizes the program description, objectives, base cases, documentation, evaluation methodology, budget, and schedule.                                                                                                                                                                                    |
| <b>First-year savings</b>               | The first full year of electrical energy or peak demand savings generated by an energy efficiency measure.                                                                                                                                                                                                                      |
| <b>Free-ridership</b>                   | Percentage of gross savings attributable to participants who would have implemented the same or similar energy efficiency measures, with no change in timing, in the absence of the program.                                                                                                                                    |
| <b>Gross savings</b>                    | Change in energy consumption and/or demand that results directly from program-related actions taken by participants in an energy efficiency program regardless of why they participated.                                                                                                                                        |
| <b>Induced consumption</b>              | Energy consumption of appliances that would have been unplugged and not replaced by participants in the absence of the program.                                                                                                                                                                                                 |
| <b>Interactive effects</b>              | Effects on the energy consumption of other systems (such as heating and cooling) in a building due to the installation of an energy efficiency measure.                                                                                                                                                                         |
| <b>In-service rate</b>                  | The proportion of incentivized products installed and operating. This rate is usually applied to programs through which rebates are offered in-store and products are likely to be stored for a certain period before being installed, such as light-emitting diode (LED) lamps.                                                |
| <b>Installation rate</b>                | The proportion of incentivized products reported as installed and that remain installed and operating at the time of evaluation. This rate is usually applied to direct install or mail-in rebate programs through which measures are expected to be installed immediately at the time of participation.                        |
| <b>Lifetime energy savings</b>          | The energy savings that occur over the lifetime of an energy efficiency measure. Lifetime energy savings account for a measure's effective useful life and any increase in the baseline efficiency level (which reduces attributable annual savings) over its lifetime.                                                         |
| <b>Line loss factor</b>                 | The multiplier to convert savings at the customer meter to savings at the utility generator. It accounts for the electrical losses of the transmission and distribution system.                                                                                                                                                 |
| <b>Margin of error</b>                  | The amount of random sampling error.                                                                                                                                                                                                                                                                                            |
| <b>Market effects</b>                   | The impact of a program on the market (in terms of product availability, practices, and prices) and that extends beyond changing program participant behaviours. Market effects include spillover among non-participants.                                                                                                       |

|                                 |                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Net savings</b>              | Electrical energy or peak demand savings that can be reliably attributed to a program. These include effects such as free-ridership and spillover that negatively or positively affect the savings attributable to a program.                                                                                                                               |
| <b>Net-to-gross ratio</b>       | The ratio of net electrical energy savings to gross electrical energy savings.                                                                                                                                                                                                                                                                              |
| <b>Non-sampling error</b>       | Errors arising during the course of all survey activities other than sampling. Non-sampling errors tend to lead to bias in measurements and are very difficult to quantify.                                                                                                                                                                                 |
| <b>Peak coincidence factor</b>  | The percentage of measure demand savings that coincide in time with the annual peak demand of the entire electricity system.                                                                                                                                                                                                                                |
| <b>Peak demand savings</b>      | The demand savings that coincide in time with the expected annual peak demand period of the entire electricity system. For industrial participants on an interruptible rate, peak demand savings may include savings on non-firm loads, i.e. loads that may be interrupted when NS Power's 10-minute reserve is low.                                        |
| <b>Precision</b>                | The extent to which repeated measurements agree with one another.                                                                                                                                                                                                                                                                                           |
| <b>Random sampling error</b>    | An error in measurement due to the fact that measurements are taken from a subset of the population and not the entire population.                                                                                                                                                                                                                          |
| <b>Realization rate</b>         | The ratio of evaluated savings to tracked savings.                                                                                                                                                                                                                                                                                                          |
| <b>Sample size</b>              | The number of observations or replicates included in a statistical sample.                                                                                                                                                                                                                                                                                  |
| <b>Secondary market impacts</b> | Energy consumption of appliances that would have been transferred to the secondary market if said appliances had not been retired.                                                                                                                                                                                                                          |
| <b>Spillover</b>                | Savings attributable to participants who implement additional energy efficiency measure(s) introduced by a program after participating in it once and without participating in the program a second time.                                                                                                                                                   |
| <b>Tracked savings</b>          | Gross and net savings calculated based on various parameters such as number of participants or units installed or sold, unitary savings values, installation rates, interactive effects, and net-to-gross ratios. Those parameters, with the exception of the number of participants or units installed or sold, are obtained from the previous evaluation. |
| <b>Unitary savings</b>          | Electrical energy or peak demand savings established on a unitary basis. A unit can either be a product (e.g. an 8 W LED lamp), a capacity (e.g. one tonne capacity of an air-source heat pump), or a participant (e.g. one participant taking part in a behaviour-based program).                                                                          |

| <b>Introduction</b>                                     | <b>1</b>   |
| <b>1 Custom Overview</b>                                | <b>2</b>   |
| 1.1 Custom Description                                  | 2          |
| 1.2 Follow-up on Past Evaluation Report Recommendations | 3          |
| 1.3 Participation History                               | 4          |
| <b>2 Custom Evaluation Approach</b>                     | <b>9</b>   |
| <b>3 Retrofit Impact Evaluation</b>                     | <b>13</b>  |
| 3.1 Tracking Sheet Audit                                | 14         |
| 3.2 Gross Savings                                       | 14         |
| 3.2.1 Savings Verification                              | 14         |
| 3.2.2 Project Review Sampling Methodology               | 14         |
| 3.2.3 Project Review Findings                           | 15         |
| 3.2.4 Interactive Effects                               | 16         |
| 3.2.5 Effective Useful Life                             | 16         |
| 3.2.6 Evaluated Gross Savings                           | 17         |
| 3.3 Net Savings                                         | 19         |
| 3.3.1 Free-ridership                                    | 19         |
| 3.3.2 Spillover                                         | 20         |
| 3.3.3 Net-to-gross Ratio Calculation                    | 21         |
| 3.3.4 Evaluated Net Savings                             | 21         |
| 3.4 Realization Rate                                    | 22         |
| <b>4 New Construction Process Evaluation</b>            | <b>24</b>  |
| 4.1 Evolution of Program Participation                  | 24         |
| 4.1.1 Subsector Participation                           | 24         |

|          |                                                                       |           |
|----------|-----------------------------------------------------------------------|-----------|
| 4.1.2    | Regional Participation .....                                          | 25        |
| 4.2      | Awareness and Motivations .....                                       | 27        |
| 4.3      | Barriers to High-Efficiency Buildings and Program Participation ..... | 28        |
| 4.4      | Participant Satisfaction .....                                        | 29        |
| 4.4.1    | Challenges Encountered.....                                           | 29        |
| 4.5      | Modeller and Participant Suggestions for Improvements .....           | 30        |
| 4.6      | Market Factors.....                                                   | 30        |
| 4.6.1    | Adoption of NECB 2020 .....                                           | 30        |
| 4.6.2    | Decarbonization and Electrification .....                             | 31        |
| 4.7      | Jurisdictional Scan.....                                              | 31        |
| 4.8      | Logic Model Review .....                                              | 34        |
| 4.8.1    | Program Objectives.....                                               | 34        |
| 4.8.2    | Barriers .....                                                        | 34        |
| 4.8.3    | Alignment of Program Logic With Barriers.....                         | 35        |
| 4.8.4    | Logic Model Summary .....                                             | 37        |
| 4.9      | Process Evaluation Highlights .....                                   | 37        |
| <b>5</b> | <b>New Construction Impact Evaluation .....</b>                       | <b>38</b> |
| 5.1      | Tracking Sheet Audit .....                                            | 38        |
| 5.2      | Gross Savings .....                                                   | 38        |
| 5.2.1    | Sampling Methodology.....                                             | 38        |
| 5.2.2    | Project Review Findings.....                                          | 38        |
| 5.2.3    | Interactive Effects .....                                             | 40        |
| 5.2.4    | Effective Useful Life .....                                           | 40        |
| 5.2.5    | Evaluated Gross Savings.....                                          | 41        |
| 5.3      | Net Savings .....                                                     | 42        |
| 5.3.1    | Free-Ridership .....                                                  | 42        |
| 5.3.2    | Net-to-gross Ratio Calculation .....                                  | 42        |
| 5.3.3    | Evaluated Net Savings.....                                            | 43        |
| 5.4      | Realization Rate .....                                                | 43        |
| <b>6</b> | <b>Building Optimization Impact Evaluation.....</b>                   | <b>45</b> |
| 6.1      | Tracking Sheet Audit .....                                            | 45        |
| 6.2      | Gross Savings .....                                                   | 45        |
| 6.2.1    | Project Review Findings.....                                          | 45        |
| 6.2.2    | Interactive Effects .....                                             | 45        |
| 6.2.3    | Effective Useful Life .....                                           | 46        |

|           |                                                           |           |

# EXECUTIVE SUMMARY

This report presents the 2024 demand-side management (DSM) results of the Custom Incentives program administered by EfficiencyOne (E1). This program is comprised of two program components: (1) Custom and (2) Strategic Energy Management (SEM).<sup>1</sup> Custom is further comprised of the Retrofit, Pay-for-Performance, New Construction, and Building Optimization services. Combined, the two program components help commercial, industrial, and institutional participants identify, prioritize, and implement energy efficiency projects, processes, or policies in their organizations by providing support, training, and financial incentives.

## Evaluation Approach

The 2024 evaluation was aimed at calculating program component gross and net results, namely electrical first-year and lifetime energy savings, peak demand savings, as well as avoided greenhouse gas (GHG) emissions. For Custom New Construction, the 2024 evaluation also included a process evaluation. Table 1 summarizes the types of evaluation conducted for each program component and the corresponding methodology.

**Table 1: Summary of 2024 Custom Incentives Program Evaluation**

| Program Component | Evaluation Type |                  |        | Methodology                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

<sup>1</sup> In 2023, SEM and Energy Management Information Systems (EMIS) were merged into a single program component. Previously, SEM and EMIS were offered as separate program components.

## Program Performance

Table 2 below presents the participation levels, average net-to-gross ratios (NTGRs), evaluated gross and net savings at the generator, annual GHG emission reductions, as well as average EUL values for each program component and for Custom Incentives as a whole.

**Table 2: Overall 2024 Custom Incentives Participation and Savings**

| *The NTGRs listed in this table match the rounded averages obtained by dividing net savings by gross savings. |                     |                                 |               |                  |       |             |                  |

Custom Incentives was aimed at achieving 31.258 GWh in net electrical energy savings and 4.571 MW in net peak demand savings at the generator for 2024. The program surpassed both the net electrical energy and demand savings targets. Custom was the largest contributor to total program net electrical energy and peak demand savings.

The following subsections present evaluation results at the program component level.

<sup>2</sup> Completed SEM projects reference participants that generated savings in a given year.

## Custom Findings and Recommendations

This section provides the key findings and recommendations from the Custom evaluation. The first key findings and recommendations apply to Custom in general, while the others are specific to certain Custom services. The recommendations are also outlined in Appendix XIV.

### Custom General Key Findings and Recommendations

**2024 Custom-Finding:** Custom achieved 39.951 GWh in net electrical energy savings and 5.225 MW in net peak demand savings at the generator in 2024, thereby surpassing the planned electrical energy savings of 27.036 GWh by 48% and the planned peak demand savings of 4.101 MW by 28%.

**2024 Custom-Finding:** While Retrofit and Building-Optimization participation levels decreased, New Construction experienced a significant increase in 2024. Overall, Custom participation decreased in 2024 compared to 2023.

**2024 Custom-Finding:** Following the project reviews, the Evaluator adjusted the electrical energy and peak demand savings for all three Custom services. For Retrofit, these adjustments resulted in adjustment ratios of 1.012 and 1.002 for electrical energy and peak demand savings respectively. Similarly, resulting adjustment ratios for Building Optimization were 1.068 and 0.899 for electrical energy and peak demand savings respectively, while New Construction saw resulting adjustment ratios of 1.028 and 1.003 for electrical energy and peak demand savings respectively.

**2024 Custom-Finding:** The free-ridership level decreased from 25% to 15% for regular Retrofit projects, while free-ridership levels were not updated for other Retrofit project categories. New Construction free-ridership decreased compared to the 2023 level and was established at 28%. Retrofit spillover was nil for regular Retrofit projects. Free-ridership and spillover were not measured for Building Optimization and were therefore maintained at 9% and 0% respectively (values from 2021).

**2024 Custom-Finding:** Evaluated net energy and peak demand savings determined by the Evaluator were both 7% higher than the savings tracked by E1.

### New Construction Key Findings and Recommendations

**2024 New Construction-Finding:** The demand savings calculation approach used by E1 for projects modelled in eQuest can generate results that are difficult to confirm.

**2024 New Construction Recommendation #1:** Review the demand savings script used for projects modelled in eQuest to ensure accurate results and favour an approach that can be applied consistently across a variety of modelling software.

**2024 New Construction-Finding:** E1 expects a large industrial New Construction project to be closed in 2025. Savings associated with the building portion were claimed in 2024, and E1 staff will conduct M&V for savings related to the industrial equipment to be installed in 2025, given the large savings generated by this measure.

**2024 New Construction Recommendation #2:** Amend section 7.10 of the New Construction program guide to require M&V for large industrial New Construction projects.

**2024 New Construction-Finding:** The share of completed projects supported by the service that are MURBs has increased in recent years, consistent with the growth of the MURB market inside the HRM.

**2024 New Construction-Finding:** The service has a higher portion of projects inside the HRM, which is to be expected. Targeting a higher number of buildings outside the HRM may require a change in building size eligibility criteria.

**2024 New Construction-Finding:** Participants are satisfied with the program overall, particularly in terms of E1's responsiveness, and are moderately satisfied with the value of the program for their business.

**2024 New Construction-Finding:** Non-participant modellers are aware of and somewhat familiar with New Construction service, including those that work on non-MURB projects.

**2024 New Construction-Finding:** Decarbonization is a motivator for participating in New Construction service.

**2024 New Construction-Finding:** Financial factors are the primary barriers for energy efficient new construction projects (higher costs of energy efficient measures, cost of energy modelling), as well as builder awareness and understanding of the benefits of energy efficient construction, and insufficient modeller participation in the service.

**2024 New Construction-Finding:** The share of modelling costs covered by the program's modelling incentive may be insufficient to motivate some builders.

**New Construction Recommendation #3:** Investigate the impact of increasing modelling incentives (the share of modelling costs covered as well as the incentive cap) on the service.

**2024 New Construction-Finding:** The service would benefit from additional energy modellers supporting the program. While historically one energy modeller supported most of the New Construction projects, E1 has worked to bring in more modellers to the program and in 2024, five energy modellers participated in the program.

**New Construction Recommendation #4:** Endeavour to recruit new energy modellers through targeted outreach; modellers put a premium on networking opportunities with builders.

**New Construction Recommendation #5:** Consider collaborating with educational institutions and professional associations for energy modelling to build a stronger pipeline of qualified and engaged energy modellers across Nova Scotia.

**2024 New Construction-Finding:** The service should prepare for the shift to NECB 2020 in Nova Scotia. Builders will need to adjust designs, plan for higher efficiency technologies and higher upfront costs, and work closely with energy modellers under the new code.

**New Construction Recommendation #6:** The program should increase targeted outreach and educational activities for builders and energy modellers related to the code shift and its impacts, particularly those involving technologies (including electrification), costs, and energy efficiency improvements. By providing practical guidance on meeting new requirements and exceeding them with the program's support, the program can position itself as a valuable resource while increasing program awareness and encouraging more participation.

**New Construction Recommendation #7:** Review the program guidelines and update to align with NECB 2020, which will be adopted in April 2025.

**New Construction Recommendation #8:** Investigate aligning implementation incentives with NECB 2020 Tiers. Such alignment would need to consider the phased-in adoption of NECB 2020 Tiers 1–3 over 2025–29.

**2024 New Construction-Finding:** The logic model is out of date and does not sufficiently document the program barriers or the activities currently being undertaken by the program to address these barriers.

**New Construction Recommendation #9:** E1 should update the Custom New Construction logic model to document and address current barriers and update the theory of change to include all activities being carried out to address these barriers.

## SEM Findings and Recommendations

This subsection provides the key findings and recommendations from the SEM evaluation. The recommendations are also outlined in Appendix XVIII.

**2024 SEM-Finding: SEM exceeded its net electrical energy and peak demand savings targets.**

In 2024, SEM achieved 4.478 GWh and 0.538 MW in net electrical energy and peak demand savings respectively. Electrical energy savings were 6% above the planned electrical energy savings of 4.222 GWh and 14% above the planned peak demand savings of 0.470 MW.

**2024 SEM-Finding: The SEM participation level has remained stable over the past five years. Electrical energy savings per participant were similar to those in 2023.**

There were 12 participants in SEM in 2024, nine continuing participants and three new participants. Moreover, seven of the 12 participants completed projects with savings in 2024, which corresponds to the average for the previous five years.

**2024 SEM-Finding: The measurement and verification (M&V) methodologies applied to quantify savings were generally appropriate and accurate. The quality of peak demand savings estimates was greatly improved compared to previous years.**

While there continued to be adjustments to electrical energy savings and peak demand savings, these adjustments were less than 1%. While not perfect, the Service Provider appears to be more consistently applying the guideline written by E1 for calculating peak demand savings.

## Program Tracked and Evaluated Savings

Table 3 below compares E1 tracked energy and peak demand savings to evaluated savings at the generator. It also includes the realization rate, representing the ratio of evaluated net savings to tracked net savings, for both energy savings and peak demand savings. Furthermore, the NTGRs are also presented and correspond to the rounded averages obtained by dividing net savings by gross savings, which explains why the NTGR values are different from those presented in the other sections.

**Table 3: Comparison of 2024 Tracked and Evaluated Savings at the Generator**

|                                                                                                               |                       | Gross Savings |      | NTGR* | Net Savings |      | Realization Rate |
|---------------------------------------------------------------------------------------------------------------|-----------------------|---------------|------|-------|-------------|------|------------------|
|                                                                                                               |                       | Value         | Unit |       | Value       | Unit |                  |
| Custom                                                                                                        | Energy Savings        |               |      |       |             |      |                  |
|                                                                                                               | Tracked Savings by E1 | 48.969        | GWh  | 0.77  | 36.918      | GWh  | 108%             |
|                                                                                                               | Evaluation Results    | 49.825        | GWh  | 0.8   | 39.951      | GWh  |                  |
|                                                                                                               | Peak Demand Savings   |               |      |       |             |      |                  |
|                                                                                                               | Tracked Savings by E1 | 6.782         | MW   | 0.71  | 5.017       | MW   | 105%             |
|                                                                                                               | Evaluation Results    | 6.774         | MW   | 0.79  | 5.255       | MW   |                  |
| SEM                                                                                                           | Energy Savings        |               |      |       |             |      |                  |
|                                                                                                               | Tracked Savings by E1 | 4.480         | GWh  | 1.00  | 4.480       | GWh  | 100%             |
|                                                                                                               | Evaluation Results    | 4.478         | GWh  | 1.00  | 4.478       | GWh  |                  |
|                                                                                                               | Peak Demand Savings   |               |      |       |             |      |                  |
|                                                                                                               | Tracked Savings by E1 | 0.537         | MW   | 1.00  | 0.537       | MW   | 100%             |

## INTRODUCTION

EfficiencyOne (E1), an independent, non-profit organization, is responsible for helping Nova Scotians improve the energy efficiency of their homes and workplaces by designing, marketing, and delivering demand-side management (DSM) for Nova Scotians. E1 provides energy efficiency, demand response, and carbon mitigation services through the Efficiency Nova Scotia (ENS) franchise. Regulatory oversight of its DSM activities is provided by the Nova Scotia Utility and Review Board (NSUARB). E1 receives funding for its electricity demand-side management (DSM) activities from Nova Scotia Power (NS Power) ratepayers.

E1 has a DSM portfolio of three residential programs, three business, non-profit, and institutional (BNI) programs, and one demand response (DR) program that are marketed to Nova Scotians through the Efficiency Nova Scotia (ENS) franchise. Each program has one or more program components. Econoler was commissioned by E1 to evaluate E1's 2024 DSM program portfolio.

This report presents the evaluation results of the Custom Incentives program comprised of two components: (1) Custom and (2) Strategic Energy Management (SEM).<sup>3</sup> Table 4 below lists the Custom Incentives program components and the types of evaluations conducted for 2024. A comprehensive impact evaluation involves reviewing the following four key elements: (1) The baseline definition; (2) the savings calculation methodology; (3) the values of the parameters used to calculate savings; and (4) net-to-gross ratios (NTGRs).

**Table 4: Types of Evaluations Conducted for Each Program Component, 2024**

| Program           | Program Component | 2024                 |        |               |
|-------------------|-------------------|----------------------|--------|---------------|
|                   |                   | Process              | Market | Impact        |
| Custom Incentives | Custom            | X – New Construction |        | Comprehensive |
|                   | SEM               |                      |        | Comprehensive |

For each program, the Evaluator prepared a DSM evaluation report presenting key findings, electrical first-year and lifetime energy savings, peak demand savings, and avoided greenhouse gas (GHG) emissions.<sup>4</sup>

<sup>3</sup> In 2023, SEM and Energy Management Information Systems (EMIS) were merged into a single program component. Previously, SEM and EMIS were offered as separate program components.

<sup>4</sup> Unless specified otherwise, energy savings refer to first-year energy savings rather than lifetime energy savings throughout this report.

# 1 Custom Overview

This section describes the Custom component of the Custom Incentives program, follows up on past evaluation recommendations, and provides an overview of participation history.

## 1.1 Custom Description

Custom provides large business, non-profit, and institutional (BNI) participants with technical assistance, financial incentives, and project financing to help reduce their electricity consumption and peak demand. Business Development Managers (BDM) also work with participants to assist them in moving their projects forward and identifying consultants. As illustrated in Figure 1, Custom includes four different services.

**Figure 1: Custom Services**

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Retrofit</b>                     | <ul style="list-style-type: none"><li>• Technical and financial support to help organizations conduct scoping and feasibility studies.</li><li>• Technical and financial support for the implementation of energy efficiency projects using a customized and flexible approach.*</li><li>• Organizations with annual consumption of 350,000 kWh or higher are eligible provided projects have not yet started.</li></ul>                                                                                                                                                                                                   |
| <b>New Construction</b>             | <ul style="list-style-type: none"><li>• Technical and financial support to achieve electrical energy savings in new buildings and for major renovations in existing buildings, excluding savings from lighting systems.</li><li>• Participation begins at the preliminary design stage to ensure the effective implementation of energy efficiency measures and achievement of maximum savings.</li><li>• Eligible facilities must be 15,000 sq ft or larger.</li><li>• Projects must achieve reductions in total building energy consumption of at least 25% and must save at least 100,000 kWh in electricity.</li></ul> |
| <b>Building Optimization (BOpt)</b> | <ul style="list-style-type: none"><li>• Technical and financial support to help organizations conduct an investigation study with the objective of improving building operational efficiency.</li><li>• Technical and financial support for the implementation of no-cost or low-cost energy efficiency measures (e.g. operating schedule changes) identified through a recommissioning process.</li><li>• Eligible facilities must not have been commissioned in the previous two years, must have a building automation system, and annually consume 350,000 kWh or more.</li></ul>                                      |
| <b>Pay-for-Performance (P4P)</b>    | <ul style="list-style-type: none"><li>• Financial support for reductions in electricity consumption achieved through a variety of capital and behavioural energy efficiency upgrades.</li><li>• Incentives are based on verified facility energy performance.</li><li>• Organizations with annual consumption of 1,000,000 kWh or higher are eligible if projects generate reductions in electricity consumption of at least 10%.</li></ul>                                                                                                                                                                                |

\* The Retrofit service also includes compressed air leak audits and solar PV projects for which a semi-prescriptive approach is used to establish evaluated savings.

EfficiencyOne (E1) claims savings for certain Custom projects over multiple years since certain phases or measures can be fully operational before an entire project is completed. There are three types of projects for which savings were tracked in 2024:

- › For projects that were not completed in 2024, the portion of savings corresponding to the savings claims submitted in 2024 were claimed as partial savings.
- › For single-year projects completed in 2024 and for which savings were only claimed in that year, all project savings were claimed as final savings.
- › For multiyear projects, which are projects with partial savings claimed in previous years and that were fully completed in 2024, the remaining portion of savings corresponding to the savings claims submitted in 2024 were claimed as final savings. Since they were completed in 2024, the 2024 adjustment ratios and NTGRs were applied to all savings for those projects.

Retrofit, P4P, New Construction, and Building Optimization combined were aimed at generating net electrical energy savings of 27.036 GWh and net peak demand savings of 4.101 MW at the generator in 2024.

## 1.2 Follow-up on Past Evaluation Report Recommendations

The Evaluator evaluated Custom in previous years and issued improvement recommendations. Table 5 below provides a summary of the implementation status of each recommendation that is still being implemented, as presented in the Executive Summary section of the 2023 Custom Incentives Evaluation Report as well as recommendations issued in the 2022 Custom Incentives Evaluation Report.

**Table 5: Implementation Status of Past Recommendations for Custom**

| #                        | Recommendations                                                                                                                                                                                                    | Status      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2022 Retrofit R2         | Require measurement and verification (M&V) efforts based on the International Performance Measurement and Verification Protocol (IPMVP) Option C approach for any Retrofit indoor horticultural lighting projects. | In progress | Program staff are currently exploring different methods to accurately represent the interactive effects associated with indoor horticultural lighting projects, including the International Performance Measurement and Verification Protocol (IPMVP) Option C approach. E1 staff are trialing a project with one customer using interactive effects calculations informed by the Efficiency Maine 2024 TRM. E1 staff estimated savings using this approach in 2024 and will conduct M&V throughout 2025 to assess the calculations used. |
| 2022 New Construction R1 | Revisit the model review process to ensure that as-built documents are used.                                                                                                                                       | Complete    | In 2024, E1 staff revised the model review and site visit templates to ensure better standardization across projects. E1 staff now use the updated documents.                                                                                                                                                                                                                                                                                                                                                                             |
| 2022 New Construction R3 | Monitor free-ridership for this service and undertake a process evaluation in 2023 or 2024 to provide recommendations on the service given the potentially shifting market and regulatory context.                 | Complete    | The Evaluator conducted a comprehensive impact evaluation of Custom New Construction in 2023, which included a review of the free-ridership algorithm to ensure different aspects of the decision-making process were captured. The free-ridership level in 2023 was established at 31%, and participant interview responses indicated changes in the market. The Evaluator conducted a process evaluation in 2024 (see Section 4).                                                                                                       |
| 2023-Retrofit-R1         | E1 should update the Custom Retrofit logic model to address current barriers and document links to other program offers such as SEM and On-site Energy Managers (OEMs).                                            | Complete    | E1 updated the Custom Retrofit logic model to include the current program barriers and links to other program offers such as SEM and On-site Energy Managers that have an impact on Custom Retrofit. Changes were updated in the program manual.                                                                                                                                                                                                                                                                                          |

## 1.3 Participation History

This subsection provides a participation overview for the four Custom services.

### Retrofit

In 2024, energy and/or demand savings were generated by a total of 88 Retrofit projects, including

- › 75 projects completed in 2024
  - › 61 single-year projects
  - › 14 multiyear projects
- › 13 projects that claimed partial savings in 2024 but were not completed:
  - › 10 projects that began in 2024 but were not completed, and for which partial savings were claimed for 2024.
  - › Three multiyear projects that began before 2024, but that were not completed and for which partial savings were claimed for 2024.

As presented in Figure 2 below, 75 completed projects generated energy savings in 2024, which is 19% lower than the 93 projects completed in 2023. However, average energy savings in 2024 per completed project increased by 17% compared to 2023. Overall, Retrofit projects achieved 24% more gross energy savings and 35% more gross peak demand savings in 2024 compared to 2023.

**Figure 2: Overview of Retrofit Participation, 2016–2024**

As illustrated in Figure 3 below, the three measure types that contributed the most to Retrofit tracked energy savings at the meter were: Compressed air leak audit, motors and solar PV measures. Also noteworthy is that out of the 75 Retrofit projects completed in 2024, eight were completed by a single participant, accounting for 41% of overall gross energy savings.

**Figure 3: Retrofit Energy Savings by Measure Type - Projects Completed in 2024**

## Pay-for-Performance

No projects generated savings under the Pay-for-Performance (P4P) service in 2024.

## New Construction

In 2024, 28 projects claimed savings under New Construction: 27 complete projects and 1 project, a new industrial facility, that was partially completed and for which savings were claimed because the building was commissioned in 2024. The building is complete and operational; however, there remains one piece of equipment to be installed before the project is finalized in 2025. As shown in Figure 4 below, following a downward trend between 2021 and 2023, the number of completed projects reached a new high in 2024. Average gross savings per project (542.091 MWh) and total program savings also reached new highs in 2024. New Construction projects generated 21.495 GWh and 4.004 MW in gross energy and peak demand savings respectively.

**Figure 4: Overview of Participation in New Construction, 2016–2024**

## Building Optimization

A total of three Building Optimization projects reported savings in 2024: two single-year projects and one project that claimed partial savings since it began in 2024 but was not completed. One of the completed projects was for a single building and the other was for the reprogramming of building operation systems for multiple schools in a school district.

While the number of projects completed in 2024 decreased compared to 2023, gross energy savings per project increased by 53%. Total gross energy and peak demand savings increased by 219% and 48% respectively compared to 2023. The large increase in total gross electrical energy savings is attributable to the uncompleted project that had a partial savings claim of 1.6 GWh.

**Figure 5: Overview of Participation in Building Optimization, 2016–2024**

## 2 Custom Evaluation Approach

The 2024 Custom evaluation comprised a comprehensive impact evaluation for Retrofit, Building Optimization, and New Construction. For Building Optimization, given its smaller contribution to Custom savings, NTGR results from 2021 were applied<sup>5</sup>. The main objectives of the 2024 Custom evaluation were as follows:

- › Calculate gross and net results, namely electrical first-year and lifetime energy savings, peak demand savings, as well as avoided GHG emissions
- › Collect information on participant and non-participant perspectives for New Construction
- › Analyze program participation for New Construction by sub-sector and by region
- › Review New Construction logic model

The Evaluator identified key research questions aimed at achieving the above objectives. Table 6 below outlines the evaluation objectives and maps them to the research questions, methods, and sample sizes (n) established by the Evaluator. Each method is described further below.

---

<sup>5</sup> Given that no projects generated savings under this service in 2024, P4P was not evaluated.

**Table 6: 2024 Custom Evaluation Approach**

| Evaluation Objectives                                                                                         | Research Questions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Methodology                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Calculate gross results                                                                                       | <ul style="list-style-type: none"> <li>› Are the data in the tracking sheet complete, accurate, and consistent?</li> <li>› Are the gross savings calculated for a sample of projects consistent with both E1 savings calculation methods and the measures implemented?</li> <li>› Have the correct EUL values been applied to sampled Retrofit project measures?</li> <li>› What are the evaluated first-year and lifetime gross electrical energy and peak demand savings?</li> </ul>                | <ul style="list-style-type: none"> <li>› Tracking sheet audits</li> <li>› Retrofit: Project reviews with either a follow-up phone interview or site visit.</li> <li>› Building Optimization: Project reviews with a follow-up phone interview.</li> <li>› New Construction: Project reviews with a follow-up phone call if required.</li> <li>› Savings verification: for Retrofit compressed air leak audit and solar PV projects.</li> <li>› Calculations using evaluation results</li> </ul> |
| Calculate net results                                                                                         | <ul style="list-style-type: none"> <li>› What are the free-ridership and spillover levels for regular Retrofit and New Construction projects?</li> <li>› What are the evaluated first-year and lifetime net electrical energy and peak demand savings?</li> <li>› What are the net avoided GHG emissions in CO2 eq for Retrofit?</li> </ul>                                                                                                                                                           | <ul style="list-style-type: none"> <li>› Participant phone interviews for Regular Retrofit, Building Optimization and New Construction</li> <li>› Calculations using evaluation results</li> <li>› Avoided GHG emission reduction calculations</li> </ul>                                                                                                                                                                                                                                       |
| New Construction: Explore opportunities to expand program presence outside of electrically heated MURB market | <ul style="list-style-type: none"> <li>› How has program participation changed over time?</li> <li>› Are projects outside of the Halifax area underrepresented in New Construction?</li> <li>› What is the awareness level about the program among non-MURB energy modellers?</li> <li>› What are the motivations and barriers for non-MURB builders to participate in the program component?</li> <li>› What actions could be taken by Custom staff to target more non-MURB participants?</li> </ul> | <ul style="list-style-type: none"> <li>› Tracking sheet analysis</li> <li>› Secondary data analysis</li> <li>› Interviews with program staff and the BDM</li> <li>› Interviews with non-participant or new energy modellers</li> <li>› Jurisdictional scan</li> </ul>                                                                                                                                                                                                                           |
| New Construction: Update program service logic                                                                | <ul style="list-style-type: none"> <li>› Does the current program logic align with participant barriers?</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                   | <ul style="list-style-type: none"> <li>› Logic model update</li> <li>› Interviews with program staff and the BDM</li> <li>› Participant and non-participant interviews</li> </ul>                                                                                                                                                                                                                                                                                                               |

## Participant Phone Interviews

To collect information on participant free-ridership and perspectives, the Evaluator conducted phone interviews with 14 regular Retrofit participants and eight New Construction participants between November 2024 and January 2025. The interview guides are presented in Appendix I for Retrofit and Appendix VIII for New Construction participants.

## Modeller Interviews

To collect information on program awareness, motivations, barriers, and views on NECB 2020 and electrification, the Evaluator conducted phone interviews with three non-participant energy modellers and two newly participating modellers (modellers who had participated for the first time in the 2024 New Construction service) between November 2024 and January 2025. The interview guide is in Appendix IX.

## Secondary Data Analysis

Econoler performed secondary research on new construction building permits in Nova Scotia to inform analysis of New Construction service participation across building types and regions. This research and analysis is summarized in Section 4.1 of this report.

## Jurisdictional Scan

Econoler carried out a scan of five new construction programs in Canada and the U.S. to inform analysis of E1's service criteria against those in other jurisdictions. This research and analysis is summarized in Section 4.7 of this report.

## Program Staff Interviews

The New Construction Program Manager and Business Development Manager were interviewed to inform the Process evaluation. The interview guide is in Appendix X.

## Logic Model Update

The Evaluator reviewed E1's most recent New Construction service logic model and theory of change and analyzed how well these address key barriers to reaching service objectives.

## Tracking Sheet Audit

Prior to performing any savings calculations, the Evaluator conducted an audit of the final 2024 tracking sheets to ensure they were complete and data entry was consistent. The detailed protocols used for the tracking sheet audits and the results obtained are presented in Appendices IV and XIII.

## Project File Reviews and Participant Site Visits or Follow-up Phone Interviews

In the fall of 2024 and January 2025, Econoler and its subcontractor CDM Energy Solutions carried out a full technical review of project documentation for 19 regular Retrofit projects, one compressed air leak regular Retrofit and two Building Optimization projects. Pursuant to the desk reviews, site visits or follow-up phone interviews with participants were conducted to finalize the project reviews. The phone interviews were also used to collect information on free-ridership and spillover for regular Retrofit participants.

In that same time period, Econoler and its subcontractor BPA conducted technical reviews of project documentation and building models for 12 New Construction projects. The information provided in the project files was sufficient to conduct reviews, thus neither follow-up phone calls, nor site visits were necessary for New Construction project reviews. Non-technical phone interviews were conducted for the reviewed New Construction projects to collect free-ridership information.

The protocol presented in Appendix V was used to review Retrofit and Building Optimization projects. The Retrofit participant interview guide is presented in Appendix I. The New Construction project review protocol is presented in Appendix XI, and the participant interview guide is presented in Appendix VIII.

## Calculations Using Evaluation Results

Building on all the above methods and collected data, the Evaluator calculated the first-year and lifetime energy and peak demand savings as per the calculation methodology presented in Sections 3, 5, and 6 below.

## GHG Emission Reduction Calculations

To obtain Custom net avoided GHG emissions in CO<sub>2</sub> eq, the Evaluator multiplied the net energy savings by the latest Nova Scotia-specific factor for GHG emissions generated by electricity production. This factor was established using Nova Scotia Power (NS Power) data.

### Note on Margins of Error

For evaluation activities that yield quantitative results based on a sample, the Evaluator aimed to achieve a maximum margin of error of 10% at a confidence level of 90%. This means that if measurements were conducted many times with different samples, the data would be within 10 percentage points above or below the percentage reported 90% of the time. Thus, the margin of error indicates the relative level of precision<sup>6</sup> of the measurement, while its associated confidence level indicates the probability of a measurement falling within the margin of error.<sup>7</sup>

As part of the 2024 Custom evaluation, the Evaluator calculated the margins of error for savings adjustment ratios for Retrofit and New Construction. No margins of error were calculated for Building Optimization since all completed projects in 2024 were reviewed by the Evaluator. The margins of error are listed alongside results in the applicable sections herein. Examples of calculations used to establish margins of error are provided in Appendix II of the 2024 DSM Programs Evaluation Executive Summary.

---

<sup>6</sup> Precision refers to how reproducible a set of measurements is. It does not take into account, however, how close the measured values are to the true values since this would refer to accuracy.

<sup>7</sup> As part of this evaluation, confidence levels and margins of error only take random sampling errors into account; they do not reflect non-sampling errors or biases such as data entry errors, inaccurate responses from respondents, or the inability to contact certain people.

### 3 Retrofit Impact Evaluation

The objectives of the 2024 Retrofit impact evaluation were to determine gross and net electrical energy and peak demand savings, annually avoided GHG emissions, as well as EUL values and associated lifetime energy savings.

As described in Subsection 1.1 above, Retrofit includes three types of savings: (1) Partial savings (projects to be completed in future years); (2) final savings for single-year 2024 projects; and (3) final savings for multiyear projects. As presented in Table 7, 13 projects achieved partial savings in 2024, 61 single-year projects claimed final savings in 2024, and 14 multiyear projects claimed final savings in 2024.

**Table 7: Evaluated 2024 Retrofit Projects**

| Type of Savings Claimed                          | Number of Projects |
|--------------------------------------------------|--------------------|
| Single-year Projects with Final Savings in 2024  | 61                 |
| Multiyear Projects with Final Savings in 2024    | 14                 |
| <b>Total Projects with Final Savings in 2024</b> | <b>75</b>          |
| Partial Savings in 2024                          | 13                 |
| <b>Total Projects Claiming Savings in 2024</b>   | <b>88</b>          |

Given the range of different project types completed in Retrofit, three distinct project categories were analyzed individually, namely (1) regular Retrofit projects; (2) solar PV projects; and (3) compressed air leak audit projects. For each project category, a distinct evaluation approach was used to determine gross and net savings. A 2024 NTGR was established for regular Retrofit projects, whereas NTGR results from the 2021 and 2023 evaluations were applied to compressed air leak audit projects and solar PV projects respectively.

Table 8 summarizes the impact evaluation approach for each project category under Retrofit. Results for the three project categories are presented below and are then combined as the aggregated results for Retrofit in Subsections 3.2.6 and 3.3.4.

**Table 8: Impact Evaluation Approach per Retrofit Project Category**

| Retrofit Project Category                                                                                                                                                                                                                                                                                                                                                                                                                        | Number of Projects Completed in 2024 | Gross Savings Methodology                                                     | Net Savings Methodology       |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|-------------------------------------------------------------------------------|-------------------------------|
| Regular Retrofit*                                                                                                                                                                                                                                                                                                                                                                                                                                | 44                                   | Adjustment ratio determined from a full review of a sample of projects (n=19) | NTGR evaluated in 2024 (n=19) |
| Solar PV                                                                                                                                                                                                                                                                                                                                                                                                                                         | 20                                   | Savings verification, applying adjustment ratios established in 2023**        | NTGR from 2023 applied        |
| Compressed Air Leak Audit                                                                                                                                                                                                                                                                                                                                                                                                                        | 11                                   | Savings verification, applying the adjustment ratio established in 2021       | NTGR from 2021 applied        |
| <p>*The regular Retrofit category includes all projects that are not included in one of the other two categories.</p> <p>**Two different adjustment ratios are applied to solar PV projects, one for projects modelled with PV Watts and one for those modelled with RETScreen Expert. These ratios were established as part of the 2023 evaluation based on modelled and measured energy production data for a sample of solar PV projects.</p> |                                      |                                                                               |                               |

## 3.1 Tracking Sheet Audit

To ensure service results were reliably compiled, the Evaluator first performed a tracking sheet audit aimed at verifying the completeness and consistency of the data submitted by E1. The verification and corrective actions taken by the Evaluator, where applicable, are described in detail in Appendix IV. The tracked savings results presented in this report therefore refer to the corrected tracked savings obtained by the Evaluator.

## 3.2 Gross Savings

Gross savings correspond to the changes in energy consumption resulting from actions taken by Retrofit participants regardless of why they participated.<sup>8</sup> E1 tracks the annual gross savings of each project. This subsection describes the methodology used by the Evaluator to review the gross savings of Retrofit projects.

E1 calculates gross savings for each individual file in accordance with best measurement and verification practices for commercial and industrial energy efficiency projects. The Evaluator used the information and data made available by participants and E1 and supplemented these with engineering assumptions and professional judgments where necessary.

### 3.2.1 Savings Verification

For compressed air leak audit and solar PV projects, the Evaluator verified savings by validating that the correct input parameters were used to estimate savings and applying a previously established adjustment ratio to tracked savings for each file to determine gross savings.

For compressed air leak audit projects, the Evaluator applied the 2021 evaluated Retrofit adjustment ratios for energy and demand savings. For solar PV projects, the adjustment ratios developed in 2023<sup>9</sup> were applied to energy savings.

### 3.2.2 Project Review Sampling Methodology

For the regular Retrofit project category, the Evaluator used a stratified sampling approach to select 19 projects for review from a total of 44 projects completed in 2024. More specifically, the Evaluator ranked projects based on their energy savings and divided them into strata. In the last stratum, which contained the largest projects, all projects were sampled while the strata of smaller projects were sampled at a lower rate. Within each stratum, projects were selected randomly. The selected sample of 19 projects represented 58% of total tracked energy savings for projects completed in 2024. Only completed projects were considered for sampling, and projects with partially claimed savings were excluded from the project reviews. Those projects will be eligible for review in a future evaluation when they are considered complete (in 2025 or later). The Evaluator obtained gross savings by extrapolating the results of the sampled project reviews to all regular Retrofit projects through a weighted average adjustment ratio.

---

<sup>8</sup> Definition adapted from National Renewable Energy Laboratory, "Chapter 23: Estimating Net Savings: Common Practices," The Uniform Methods Project, September 2014, p. 3, available at: [http://energy.gov/sites/prod/files/2015/02/f19/UMChapter23-estimating-net-savings\\_0.pdf](http://energy.gov/sites/prod/files/2015/02/f19/UMChapter23-estimating-net-savings_0.pdf) (last accessed November 19, 2015).

<sup>9</sup> In 2023, two distinct adjustment ratios were developed, one for projects using Retscreen to estimate annual solar PV energy generation, and another for projects using PV Watts.

In addition to the 19 regular retrofit projects reviewed, the Evaluator considered two very large compressed air leak audit projects for review. These projects generated 3.7 GWh and 4.0 GWh in tracked gross electrical energy savings and were completed by the same participant. The savings were established using a different methodology and leak detection device than what are typically used by Retrofit participants carrying out compressed air leak audit and repair projects. Instead of following the typical process through which an E1 staff member conducts the initial and follow-up compressed air audits, the E1 on-site energy manager (OEM) assigned to this project guided the participant to track and report electrical energy savings using an alternative leak detection device. As a result of this deviation from the standard process and given the scale of the savings claimed, these projects were subject to a more thorough review than the other compressed air leak projects that typically undergo a more streamlined evaluation process in the form of a savings verification (as described in Subsection 3.2.1 above). Given that both projects were completed by the same participant and relied on the same type of documentation and savings calculation methodology, the Evaluator conducted an in-depth review of only one of them.

### 3.2.3 Project Review Findings

The Evaluator reviewed the project sample to ensure the best measurement and verification practices were applied for commercial and industrial energy efficiency projects and adjusted the tracked savings accordingly.

#### Regular Retrofit Project Reviews

As a result of the review process, the Evaluator adjusted the savings of eight of the 19 sampled regular Retrofit projects. These are broken down as three projects having a combination of energy and peak demand adjustments, and five projects having only peak demand savings adjustments.

Of the three projects for which both energy and peak demand savings were adjusted:

- › One project involved upgrades to a building envelope. The Evaluator visited this project as part of the project review and noticed that the actual insulation value of what was installed was higher than what was used for the energy savings calculations. The Evaluator thus updated the calculation to use the observed insulation values, resulting in increased energy and demand savings.
- › One project had correctly calculated the energy and demand savings in the M&V project files; however, the savings recorded in the tracking sheet were based on the pre-M&V estimations. The Evaluator updated the savings to reflect what was calculated post-M&V, resulting in a downward adjustment to the energy and demand savings.
- › One project involved replacing an industrial motor with a more efficient version. Originally, the savings were calculated based on the operational energy consumption. However, when reviewing the M&V file, the Evaluator observed energy savings while the motor was in idle mode, as well as savings resulting from the removal of a motor cooling fan. The Evaluator made a slight upward adjustment to the energy savings of this project. The Evaluator made a downward adjustment to this project's demand savings due to a calculation error; similarly to the energy savings, the demand savings were only considered during the operational period of this project. However, the motor's operational schedule was sporadic, and there was no pattern observed to indicate that it would be consistently operational through the peak demand window. Thus, the Evaluator recalculated the peak demand savings to be the average demand savings.

Many of the projects claimed in retrofit are industrial processes, and therefore often have somewhat random operating schedules. For situations like this, the peak demand savings are best approximated as the average annual savings. For the five projects where only peak demand savings were adjusted, all were adjusted to more accurately estimate demand savings occurring during the peak periods. This resulted in three downward adjustments and two upward adjustments to peak demand savings.

In light of these adjustments, the Evaluator suggests that E1 review the peak demand savings calculation best practices for Retrofit projects to ensure they properly represent demand savings occurring during the peak period.

The Evaluator used the above adjustments to calculate average adjustment ratios for energy and peak demand savings for the project sample (results are provided in Subsection 3.2.6 below).

### Compressed Air Leak Audit Project Review

The Evaluator also conducted an in-depth review of one of two large compressed air leak audit projects completed by the same participant at two different facilities. These projects were conducted using an all-in-one platform for leak locating and repair tracking, which is a different technology than what is typically used for compressed air leak audits. For the project that was reviewed, the process involved three elements:

- › A desktop review of the calculation sheets and leak detection platform documentation
- › A phone interview with the E1 OEM who actively supported the participant through the project to validate project parameters as well as the leak audit and repair process
- › An on-site demonstration of the leak detection device performed by a technician from the participating organization

Following the project review, the Evaluator considers the leak detection and repair process used by the participant to be sound and reliable. The provided project documentation and savings calculation methodology were also found to be accurate and of sufficient detail. The Evaluator also notes that the technical expertise of the OEM and participant staff was appropriate and contributed to the quality of the project and reliability of the estimated savings. As a result, the Evaluator made no adjustments to the electrical energy and peak demand savings tracked by E1, resulting in an adjustment ratio of 1.0 for the reviewed project. This adjustment ratio was also applied to the other large compressed air leak audit project completed by this participant.

### 3.2.4 Interactive Effects

Since interactive effects vary significantly from one Retrofit project to another, they are taken into account in the project engineering calculations used to obtain initial gross savings. Any adjustments required to interactive effects were made as part of the project review.

### 3.2.5 Effective Useful Life

The Evaluator reviewed the EUL values of all sampled projects by selecting an appropriate EUL for each measure implemented. The revised measure level EUL values were selected based on the values outlined in the 2024–2025 Demand-Side Management Measure Assessment (DSM MA).

Following the review of the 19 sampled regular Retrofit projects, the Evaluator found that four of those projects required adjustments to their EUL values. The changes made by the Evaluator stemmed from a better understanding of the measures implemented through project reviews. For example, two projects implemented multiple energy saving measures, such as LED lighting, a central heat plant, and building automation system upgrades, each of which has a different EUL. For both of these projects, the EUL was tracked for only one of the measures, so the Evaluator adjusted the project EUL to be a weighted average of each measure's EUL based on the savings attributed to each measure.

Following the savings verification performed on compressed air leak audit projects, the Evaluator adjusted the EUL of all projects from four years to two years, as presented in the 2024–2025 DSM MA.

For solar PV projects, the Evaluator adjusted the tracked 25-year EUL to 30 years. This is in line with the value tracked in the 2024–2025 DSM MA.

### 3.2.6 Evaluated Gross Savings

Savings for Retrofit are claimed under three defined categories: (1) Partial savings; (2) final savings for single-year 2024 projects; and (3) final savings for multiyear projects. For projects that claimed partial savings in previous years and were completed in 2024, the Evaluator calculated a true-up adjustment. This true-up adjustment is added to the total adjusted gross savings claimed over the years so that the sum is equivalent to the total tracked project savings multiplied by the adjustment ratio determined for the year of project completion. The Evaluator applied a distinct current-year adjustment ratio to the savings of each project category under Retrofit based on the approaches described in Subsections 3.2.1 and 3.2.2 above. These adjustment ratios are presented in Table 9 below. The Evaluator aggregated results from all project categories to determine overall evaluated gross savings for Retrofit.

**Table 9: 2024 Retrofit Adjustment Ratios per Project Category**

| Retrofit Project Category                                                                                                                                                                      | Adjustment Ratio on Energy Savings (Margin of Error) | Adjustment Ratio on Demand Savings (Margin of Error) |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|------------------------------------------------------|
| Regular Retrofit                                                                                                                                                                               | 1.021 (±4.9%)                                        | 1.001 (±0.2%)                                        |
| Solar PV - PV Watts                                                                                                                                                                            | 1.101 (±2.3%)                                        | N/A *                                                |
| Solar PV - RETScreen                                                                                                                                                                           | 0.942 (±4.2%)                                        | N/A *                                                |
| Compressed Air Leak Audit                                                                                                                                                                      | 0.981 (±1.2%)**                                      | 1.007 (±4.8%)**                                      |
| *The energy generated by solar PV systems coinciding with the Nova Scotia peak periods is considered nil, and none of the solar PV projects completed in 2024 had tracked peak demand savings. |                                                      |                                                      |
| **Adjustment ratios were not calculated for compressed air leak audit projects in 2024. Instead, the 2021 Retrofit adjustment ratios were used.                                                |                                                      |                                                      |

Table 10 presents an example of how the true-up adjustment was applied to the gross energy savings of a multiyear project completed in 2024.

**Table 10: Example of a 2024 True-up Adjustment**

|                                                                       | 2023    | 2024    | Total          |

Table 11 below presents the overall evaluated gross savings for Retrofit, which were obtained by applying the appropriate adjustment ratios from Table 9 above to each project's energy savings and peak demand savings and by applying true-up adjustments to the final savings of multiyear projects completed in 2024. The adjustment ratios presented in Table 11 are the resulting adjustment ratios for each type of savings claimed in Retrofit and are obtained by dividing gross savings without true-up adjustments by tracked savings. Savings at the generator were calculated using line loss factors that account for electricity losses occurring between the meter and the generator. For each project, the Evaluator applied energy and peak demand line loss factors corresponding to the relevant rate code based on the values drawn from the

| <p>* The adjustment ratios listed in this table are the averages obtained by dividing gross savings without true-up adjustments by tracked savings. They differ from the values presented in Table 9 above because of the different adjustment ratios applied to each project category.</p> <p>** The line loss factors are average values obtained by dividing gross savings at the generator by gross savings at the meter. Each retrofit project received its own specific line loss factor based on participant rate codes.</p> <p>*** These EULs are average EUL values obtained by dividing gross lifetime energy savings by gross energy savings. Each retrofit project received its own specific EUL to obtain lifetime savings.</p> |                         |                                                |                                              |                |

As presented in Table 12 below, GHG emission reductions were calculated by applying the Nova Scotia-specific factor<sup>12</sup> for GHG emissions generated by electricity production to Retrofit gross savings.

<sup>10</sup> Nova Scotia Utility and Review Board, Matter M06555, 2014 Cost of Service Study Progress Update, Exhibit N-2.09, Appendix I1.

<sup>11</sup> For municipal utility participants, the line loss factor of the most similar NS Power rate code was assumed.

<sup>12</sup> At the time of writing, 2024 data were not yet available. The Nova Scotia-specific factor was obtained from Nova Scotia Power's 2023 total system emissions data (4,931,152 CO<sub>2</sub> eq tonnes), and total electricity generation (10,442 GWh) was drawn from the following two sources: Nova Scotia Power, Total System Emissions, <https://www.nspower.ca/clean-energy/air-emissions-reporting> (last accessed September 27, 2024) and Emera Inc., Emera Inc. 2023 Annual Report, p. 31, available at [https://s25.q4cdn.com/978989322/files/doc\\_financials/2023/ar/Emera\\_2023\\_AR\\_FINAL.pdf](https://s25.q4cdn.com/978989322/files/doc_financials/2023/ar/Emera_2023_AR_FINAL.pdf) (last accessed September 27, 2024).

### 3.3 Net Savings

The Evaluator determined net energy and peak demand savings, that is, the electrical energy and peak demand savings that can be reliably attributed to a service, by estimating an NTGR. Specifically, the NTGR includes effects such as free-ridership and spillover that positively or negatively affect the energy savings generated by a service. For Retrofit, free-ridership and participant spillover are both considered in the NTGR.

For each of the three Retrofit project categories, the Evaluator determined a distinct NTGR. Table 13 describes the approach used to determine the NTGR for each project category.

**Table 13: 2024 NTGR Approach per Retrofit Project Category**

| Retrofit Project Category                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Number of Projects Completed in 2024 | NTGR Methodology                                                                                    | Sample Size (Unique Participant Interviews) * |

| <p>*If a participant completed more than one project sampled for review, only one interview was conducted. The associated NTGR was applied to all projects completed by that participant unless they indicated that their decision-making process differed across projects, in which case a distinct NTGR was calculated for each project.</p> <p>**Although the evaluation methodology included a sample size of n=19, only 14 of the sampled participants from 16 projects were reached, despite multiple efforts to contact participants.</p> |                                      |                                                                                                     |                                               |

#### 3.3.1 Free-ridership

In the case of Retrofit, free-ridership occurs when participants would have still implemented energy efficiency upgrades and measures in the absence of the service.

For compressed air leak audit projects, the NTGR was not measured in 2024; therefore, the 2021 NTGR was applied since the 2021 project sample used to assess free-ridership included compressed air leak audit projects. Similarly, the free-ridership level was not measured for solar PV projects in 2024; however, it was measured in the 2023 evaluation using a self-report approach. Therefore, the 2023 solar PV free-ridership level was used in the 2024 evaluation.

For the regular Retrofit project categories, the corresponding 2024 free-ridership level was assessed using a self-report approach that involved asking participants a set of questions during phone interviews. The questionnaire included questions for all applicable variables in the decision-making process, including planning, efficiency, timing, cost, and E1 influence through financial incentives or participant support from program staff or OEMs. Certain questions were also used to determine the extent to which participant decisions about whether to implement measures or not had been influenced by previous participation in an E1 program component or E1 efforts to raise awareness about energy efficiency. When participant answers indicated that they had been significantly influenced by one of these two factors, the free-ridership level was adjusted downward to better reflect the overall influence of E1 activities on participant decisions. The feedback collected from participant interviews was converted into an overall free-ridership level using the algorithm presented in Appendix II.

The free-ridership level calculated for each project category is presented in Table 14 along with the corresponding margin of error.

**Table 14: 2024 Retrofit Free-ridership Level per Project Category**

| Retrofit Project Category                                                                                                                                                 | Free-ridership Level | Margin of Error |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|-----------------|
| Regular Retrofit                                                                                                                                                          | 15%                  | 2.90%           |
| Solar PV                                                                                                                                                                  | 38%*                 | 9.5%*           |
| Compressed Air Leak Audit                                                                                                                                                 | 16%**                | 10.6%**         |
| *Free-ridership for solar PV projects was not measured in 2024; the free-ridership level from the 2023 evaluation is presented here for reference only.                   |                      |                 |
| **Free-ridership for compressed air leak audit projects was not measured in 2023; the free-ridership level from the 2021 evaluation is presented here for reference only. |                      |                 |

For regular Retrofit projects, the free-ridership level was established at 15% for 2024, representing a 10% decrease compared with 2023. E1 influence on participant decision-making was the most significant factor contributing to the decrease in the free-ridership level, with 12 of the 14 unique regular Retrofit respondents indicating that E1 influence was very important in their decision to implement their project.

For regular Retrofit projects, the project sampling methodology is based on energy savings because incentives for these projects have historically been paid based on energy savings. Therefore, consistent with past evaluations, free-ridership was calculated based on the energy savings for these project categories, and the resulting NTGR was applied to both energy and demand savings to establish net savings for both parameters.

As in previous evaluations, the Evaluator considered the free-ridership level for each project category to be representative of the balance of projects in the project tracking sheet given that the margins of error were below the 10% target for this parameter.

### 3.3.2 Spillover

For Retrofit, participant spillover occurs when participants implement eligible energy efficiency measures due to the influence of previous participation in the service without receiving any kind of additional support<sup>13</sup>. The Evaluator used phone interviews to question participants directly about any potential spillover effects. The algorithm used to determine the level of participant spillover is presented in Appendix III.

<sup>13</sup> Participant spillover may also include measures implemented by past Retrofit participants. No projects from past participants were brought forward from E1 for consideration in 2024.

Among the 14 unique respondents from regular Retrofit participants, one mentioned having implemented energy efficiency measures on their own and that their participation in Custom Retrofit was “somewhat influential” on their decision to implement the measures. The participant mentioned that the project was a motor retrofit, and that the associated energy savings were estimated at under 10,000 kWh. Using these findings, the Evaluator calculated the spillover level to be nil for regular Retrofit.

### 3.3.3 Net-to-gross Ratio Calculation

The NTGR was calculated using the following equation:

$$NTGR = (1 - \% \text{ Free-ridership} + \% \text{ Participant Spillover})$$

Table 15 outlines the free-ridership and spillover levels established for Retrofit along with the NTGR values calculated for each project category.

**Table 15: Evaluated 2024 Retrofit NTGRs**

| Project Category                                                                                                                                                       | Free-Ridership Level | Spillover Level | NTGR |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|-----------------|------|
| Regular Retrofit                                                                                                                                                       | 15%                  | 0%              | 0.85 |
| Solar PV*                                                                                                                                                              | 38%                  | 1%              | 0.63 |
| Compressed Air Leak Audit**                                                                                                                                            | 16%                  | 0%              | 0.84 |
| *Free-ridership and spillover solar projects were not measured in 2024; the values from the 2023 evaluation are presented here for reference.                          |                      |                 |      |
| **Free-ridership and spillover for compressed air leak audit projects were not measured in 2023; the values from the 2021 evaluation are presented here for reference. |                      |                 |      |

### 3.3.4 Evaluated Net Savings

Net savings are defined as changes in energy use that are specifically attributable to Retrofit. Net Retrofit impacts are calculated by applying the NTGR value to gross savings as illustrated in the following equation:

$$\text{Net Savings} = \text{Gross Savings} \times \text{NTGR}$$

The Evaluator applied the corresponding NTGR to the gross savings generated in each project category under Retrofit. The evaluated NTGRs are presented in Table 15 above. The Evaluator aggregated results from all project categories to determine overall evaluated net savings for Retrofit.

The Evaluator applied a true-up adjustment to the net energy savings of multiyear projects completed in 2024 so that the total revised net savings over the complete duration of each project are equivalent to the total revised gross project savings multiplied by the appropriate NTGR for 2024. This approach is similar to the one described in Subsection 3.2.6 above.

The results are listed in Table 16 below. The average EUL was established at 8.5 years, and the net energy savings resulted in 10,567 tonnes of CO<sub>2</sub> eq in net annual GHG emission reductions.

**Table 16: Evaluated 2024 Retrofit Net Energy and Peak Demand Savings**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Partial Savings Claimed | Final Savings Claimed for Single-year Projects | Final Savings Claimed for Multiyear Projects | Total          |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|------------------------------------------------|----------------------------------------------|----------------|
| <b>Energy Savings</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                         |                                                |                                              |                |
| Gross Energy Savings – at the Meter (GWh)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 13.041                  | 9.644                                          | 2.339                                        | 25.025         |
| NTGR*                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0.84                    | 0.81                                           | 0.85                                         | 0.83           |

| <p>*The NTGRs listed in this table match the rounded averages obtained by dividing net savings by gross savings. They differ from the values presented in Subsection 3.3.3 above because of true-up adjustments and the different NTGRs applied to each project category.</p> <p>**The line loss factors are average values obtained by dividing gross savings at the generator by gross savings at the meter. Each retrofit project received its own specific line loss factor depending on participant rate codes.</p> <p>***These are average EUL values obtained by dividing gross lifetime energy savings by gross energy savings. Each retrofit project received its own specific EUL to obtain lifetime savings.</p> |                         |                                                |                                              |                |

### 3.4 Realization Rate

Table 17 below compares the total 2024 tracked and evaluated savings for Retrofit. It also includes the realization rate, representing the ratio of evaluated net savings to tracked net savings, for both energy savings and peak demand savings.

**Table 17: Comparison of 2024 Retrofit Tracked and Evaluated Savings at the Generator**

|                                                                                                                                                                                                                                                                         | Gross Savings |      | NTGR* | Net Savings |      | Realization Rate |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|------|-------|-------------|------|------------------|

| Evaluation Results                                                                                                                                                                                                                                                      | 26.355        | GWh  | 0.86  | 22.677      | GWh  |                  |
| Peak Demand Savings                                                                                                                                                                                                                                                     |               |      |       |             |      |                  |
| Tracked Savings by E1                                                                                                                                                                                                                                                   | 2.688         | MW   | 0.81  | 2.169       | MW   | 106%             |
| Evaluation Results                                                                                                                                                                                                                                                      | 2.691         | MW   | 0.85  | 2.289       | MW   |                  |
| * The NTGRs listed in this table match the rounded averages obtained by dividing net savings by gross savings. They differ from the values presented in Subsection 3.3.3 above because of true-up adjustments and the different NTGRs applied to each project category. |               |      |       |             |      |                  |

Evaluated gross energy savings were higher than the tracked gross energy savings primarily due to the adjustment ratio being above one. Evaluated net energy and peak demand savings were higher than tracked savings because the 2024 evaluated NTGR was higher than the NTGR tracked by E1.

## 4 New Construction Process Evaluation

Results from the New Construction process evaluation are presented below. Subsection 4.1 provides an overview of the evolution of service participation during 2019–2024. Subsections 4.2–4.6 cover awareness, motivations, barriers, participant satisfaction, and perspectives on market factors that could impact the service, notably upcoming changes to the building code and decarbonization. Subsection 4.7 summarizes a jurisdictional scan of New Construction programs and finally, Subsection 4.8 focuses on a review of the logic model.

### 4.1 Evolution of Program Participation

The New Construction service supported a total of 100 completed new construction projects over the 2019–2024 period, with an average of 17 projects per year. The year 2024 saw the greatest number of projects since 2019, with 27 completed projects and one partially completed project for which savings were claimed. The Evaluator reviewed the program tracking data to investigate the characteristics of New Construction projects over time, notably the number of multi-residential buildings (MURBs) as compared to non-MURBs, and the number of projects inside and outside the Halifax Regional Municipality (HRM). This analysis was used to determine whether there are underrepresented markets that could be opportunities for the program service.

#### 4.1.1 Subsector Participation

As shown in Figure 6,<sup>14</sup> MURBs have made up most of the New Construction projects since 2022. MURB and non-MURB participation was about equal during 2020 and 2021, then non-MURB participation decreased in 2022 while MURB participation grew. Even as overall participation slightly declined, the proportion of projects that were MURBs remained high in 2023 and remained high as participation significantly grew in 2024.

**Figure 6: Participation by MURB and Non-MURB Building Types, 2019–2024**

<sup>14</sup> Figure includes projects completed in 2024. It does not include projects for which the service claimed partial savings.

Econoler reviewed available secondary data to assess trends in MURB and non-MURB new construction in Nova Scotia. Multiple publicly available datasets were investigated; however, data providing information on building size, building type, and region for Nova Scotia was not found. Nevertheless, HRM building permit data for 2021–2024 that includes building size and type was identified from the Halifax Data, Mapping and Analytics Hub.<sup>15,16</sup> Econoler identified records for buildings larger than 15,000 sq ft<sup>17</sup> (in line with service eligibility requirements) and categorized permits as MURB or non-MURB. The data does not include building heating sources. According to these data, MURBs accounted for a large majority of eligible newly permitted buildings in the HRM over the 2021–2024 period. The data also show that while they comprise a lower portion of permits than MURBs, the number of permits for non-MURB buildings has also significantly increased. Statistics Canada also collects new construction permit data,<sup>18</sup> though this data does account for building size and therefore includes permits for buildings less than 15,000 sq ft that would be ineligible for the service. This data shows that two-thirds of all new permits inside the HRM during 2019–2023 were MURBs, with little variation year-over-year. Neither data source on building permits is definitive; therefore, results should be interpreted with caution. The share of completed projects participating in the NC service that were MURBs significantly increased from 48% in 2021 to 89% in 2024, indicating that the program is generally following the MURB market in the HRM, although there may be additional opportunities to capture the growing non-MURB market. To enable this, the service could conduct an analysis to identify high-opportunity non-MURB sectors, including relevant stakeholders, and develop targeted outreach and engagement plans for these sectors.

E1 program staff explained that population growth inside the HRM has encouraged the construction of more and more large MURBs, and these have gained traction in the service. Program staff said that industry groups such as architecture and engineering firms tend to drive non-MURB design, and working with these firms early in the design phase could lead to more non-MURB participation. According to program staff, the service has hired more Energy Managers with non-MURB experience, and there was more interest in the service from the education sector and industry in 2024 than in previous years.

There was limited data available for areas outside the HRM. Over 2019–2024, the service reached 10 non-MURB buildings and 7 MURB buildings outside the HRM. E1 staff explained that one reason why fewer MURBs outside the HRM are reached than inside the HRM is that these buildings tend to be at the smaller end of program size eligibility requirement, and for these buildings' developers the cost of energy modelling could be high relative to the total service incentive. Program staff believe that public sector buildings are the biggest non-MURB opportunity outside the HRM. The breakdown of inside versus outside the HRM is discussed further below.

### 4.1.2 Regional Participation

Econoler reviewed program tracking data and identified which projects occurred inside and outside the HRM. There were 83 projects inside and 17 outside the HRM during the 2019–2024 period.

---

<sup>15</sup> Halifax Data, Mapping and Analytics Hub: [https://data-hrm.hub.arcgis.com/datasets/f0736e6d03364a348f402c73663e503d\\_0/explore](https://data-hrm.hub.arcgis.com/datasets/f0736e6d03364a348f402c73663e503d_0/explore).

<sup>16</sup> Analysis of older permit data (2019–2020) showed that building area was missing for 86% of applicable records; therefore, it was not included.

Halifax Data, Mapping and Analytics Hub: [https://data-hrm.hub.arcgis.com/datasets/9f7705cb4ca643a7941a6273d2214750\\_0/explore](https://data-hrm.hub.arcgis.com/datasets/9f7705cb4ca643a7941a6273d2214750_0/explore)

<sup>17</sup> Building footprint data is included in the 2021–2024 dataset. The building footprint is the ground-level area covered by a building, including walls but excluding open spaces like yards. Building area is the total floor area of a building, including all stories. Building area was estimated by multiplying the building footprint area by the number of stories.

<sup>18</sup> Statistics Canada: <https://www.statcan.gc.ca/en/subjects-start/construction>.

**Figure 7: Participation Inside and Outside the HRM, 2019–2024**

The HRM contains 50% of Nova Scotia's population so, given the population density, a higher proportion of projects inside the HRM would be expected. The Evaluator found minimal data on new construction outside the HRM. Statistics Canada has new construction data for Nova Scotia from 2019–2023,<sup>19</sup> but it does not include information on building size or fuel type and, therefore, contains permit information for certain buildings that would not be eligible for the service. Because of this, results should be interpreted with caution.

Permit data shows that between 2019 and 2023 there has been significant growth in the number of building permits issued both inside and outside the HRM.<sup>20</sup> Over the five-year period, the service reached a higher share of permitted new construction projects in the HRM (5%) than outside of the HRM (<1.0%).<sup>21</sup> The Evaluator believes that this is partly due to a larger portion of the new buildings outside the HRM being smaller, and thus ineligible for the service. For example, E1 staff explained that building rules inside the HRM streamline permitting processes and encourage larger and faster-built buildings, whereas conditions outside the HRM are unfavourable for larger buildings. Larger buildings outside the HRM already tend to participate in the service, according to staff. Overall, and although program eligibility requirements and municipal building rules limit these opportunities to some degree, this information indicates that there may be some opportunity for the service to widen its reach outside the HRM.

While insufficient modelling support could be seen as a barrier outside the HRM, all five energy modellers interviewed for this evaluation confirmed that they conduct modelling for projects outside the HRM. To increase participation outside the HRM, non-participant energy modellers recommend improving outreach efforts and tailoring messaging to the specific needs of rural builders; for example, oil-based systems are common outside the HRM, and builders are less experienced with heat pumps. They claim that program awareness is lower outside the HRM due to limited client-facing engagement and advocate for in-person outreach, such as program representatives visiting developer offices or municipalities. Other recommendations include creating platforms or roadshows to directly present the service's benefits to rural builders, as many are too busy to independently seek out information (see Subsections 4.2-4.4 for analysis of energy modeller interviews).

<sup>19</sup> Statistics Canada: <https://www.statcan.gc.ca/en/subjects-start/construction>.

<sup>20</sup> On average, 24% growth per year inside the HRM and 15% per year outside the HRM.

<sup>21</sup> Calculated as the total number of program projects completed inside the region during the period, divided by the total number of permits issued during the period. The total number of permits includes buildings of <15,000 sq ft

## 4.2 Awareness and Motivations

This section presents the findings from interviews with two newly participating modellers and three non-participant modellers to understand their awareness of the program, and perspectives on the motivation of their non-participating builder clients for completing high-efficiency buildings. Below is a brief profile of the modellers interviewed:

- › Two modellers reported that the majority of their energy modelling business in Nova Scotia is for MURBs, whereas the other three modellers conduct most or the majority of their work for institutional and government clients.
- › Three modellers complete energy modelling almost equally between organizations located within the HRM and those outside the HRM, while one modeller conducts most of its work in the HRM (though still does some work outside the HRM), and the other focuses on clients outside the HRM.
- › Two modellers said that all the buildings they model are larger than 15,000 square feet, while the others report their work being equally divided between buildings of that size and smaller.
- › Three modellers do the majority or all of their energy modelling for electrically-heated buildings, while one non-participant modeller focuses on gas-heated buildings, and another modeller's business is divided between heating sources.

All three non-participant modellers were aware of Custom New Construction, either being very (n=1) or somewhat (n=2) familiar with the program. Two non-participant modellers said they could not recall how they heard about the program, and one said they had spoken with an E1 representative. There was no difference in awareness levels between modellers who work more with MURBs versus those who work more with non-MURBs.

Of the three modellers that never took part in Custom New Construction, only one discussed the program with the builders they work with, while the others did not. This modeller said they typically bring up the topic with clients, but that the idea is usually quickly dismissed. By contrast, the two modellers new to the program reported a different experience: one noted the program is typically mentioned by clients, while another new modeller suggested that the idea usually arises from a discussion between their business and the client.

Modellers reported that their clients complete an energy model for a variety of reasons, notably to increase long-term investment value through more energy efficient design (n=4), but also to identify systems that provide the lowest operational costs (n=2) as a requirement for energy efficiency incentive programs (n=2) or for code compliance<sup>22</sup> (n=2). One modeller also mentioned clients use modelling in support of meeting organizational energy savings or GHG reduction targets.

According to modellers interviewed, there are several reasons why builders decide to design higher energy efficiency buildings that exceed building code requirements. All believe that clients are motivated by the prospect of reducing or controlling their building's operational costs and/or to protect against rising energy costs. Sustainability and climate change are important drivers: most mentioned that their clients are following corporate sustainability values, whether it be achieving net-zero or reducing GHG emissions (n=4). Two non-participant modellers also said some clients are looking to satisfy market demand for sustainable or green buildings, and two said that some clients want to meet government mandates and/or climate goals. Builders also want to achieve higher rent potential, and/or enhance tenant comfort or satisfaction. One modeller suggested that some clients are also motivated to design energy efficient properties that exceed building codes to access financing or incentives.

---

<sup>22</sup> NECB 2017 Performance Path requirement.

### 4.3 Barriers to High-Efficiency Buildings and Program Participation

Participating builders, non-participant modellers, and new energy modellers were asked about concerns and barriers related to building high-efficiency buildings.

When asked what their primary concerns were when considering building high-efficiency buildings, participating builders mostly cited financial factors (n=8), including measure costs, profits, payback period or return on investment (ROI), construction costs, and operational costs. The performance of energy efficient technologies was cited by three builders, particularly equipment reliability given the region's cold climate. Concerns were also raised about a lack of local expertise in the design, installation, and operation of efficient technologies (n=2).

Participant builders were also asked if there were any additional higher-efficiency technologies they would have liked to have installed, but which were not included in their project. Three of the eight participants considered additional measures in their new construction project that were then dismissed because of cost. Two considered extra solar panels but did not proceed due to the costs of solar technology, anticipated maintenance expenses, and added installation time. The third participant considered air-to-water heat pump water heaters but cited low incentives as the reason for not installing them.

Financial factors were also cited by non-participant and newly participating energy modellers as an important barrier for the clients they work with (n=4). At the same time, modellers reported that builders may not realize the value proposition of building above the minimum code, especially because energy efficiency code requirements have become more stringent, and some builders do not see the value added in exceeding code (n=3). In addition, builders may lack a clear understanding of the range of measures and their respective impacts on energy efficiency, beyond heating systems. One modeller also mentioned that builders—given their lack of understanding of the value proposition related to a more efficient building—seem more focused on including better fixtures and finishes in their design than on enhancing energy efficiency. Another modeller believed that energy efficiency, or sustainable building, is not a primary focus for some builders. Note that the responses were generally consistent between modellers working mostly for MURBs and those working mostly for non-MURBs.

Cost is also a key barrier for energy modelling. Most non-participant and new energy modellers believed that some builders chose not to complete an energy model for their building primarily because modelling is too expensive (n=4). Two energy modellers said that builders think the additional time for modelling will cause project delays, and two said that builders are unaware of the benefits of energy modelling.

The three non-participant modellers interviewed mentioned gave several reasons for not participating in the program. Reasons cited include that clients did not mention they were taking part in Custom New Construction, that the builders they work with do not feel incentivized to exceed code requirements, that modelling incentives do not account for the time spent by the modeller coordinating between the program and the client, and that the cost of energy modelling is disproportionately high compared to building costs for smaller projects. One of the modellers mentioned a lack of awareness about the program and uncertainty about the next steps as a consultant, which stalled their participation.

## 4.4 Participant Satisfaction

There is a relatively high level of participant satisfaction with Custom New Construction overall, leading to an average satisfaction score of 7.9 out of 10, on a scale where a score of 1 means “not at all satisfied” and 10 means “very satisfied”. Satisfaction is highest with E1 employees’ responsiveness to requests and inquiries in a timely manner (average score of 8.9), the speed with which the application was approved (8.5), and E1 employees’ technical expertise related to the program (7.8). There is also satisfaction with the value of the program or service in relation to the time and cost (7.1) and the ability to estimate the savings or return on investment associated with the program (6.9), although to a lesser extent.

**Figure 8: Satisfaction With Custom New Construction, 2024**  
Highly Satisfied (Marks of 8–10)

Participants’ dissatisfaction was mainly related to the low level of implementation incentive (n=4), especially for larger, more complex projects such as geothermal, the desire for more timely application approvals, and the need for more information on energy consumption savings.

### 4.4.1 Challenges Encountered

Only two participants reported that their company had experienced challenges with Custom New Construction in the past year. One of them said there was a delay in guidance from E1 on the eligibility of a measure for a project, and that the final decision to allow the measure was not communicated by E1 to them in time for them to adapt their building design accordingly. The other participant felt that the program does not adequately incentivize the construction of “hyper”-efficient buildings.

## 4.5 Modeller and Participant Suggestions for Improvements

Participants shared a number of suggestions for improving Custom New Construction, including conducting outreach to developers and builders to inform them of available incentives; focusing on energy efficiency more broadly, rather than only incentivizing electric savings; implementing a tiered approach that pays higher incentives for larger and more complex buildings; and ensuring that incentives are distributed to project developers in a timely and consistent manner.

Non-participant and newly participating modellers were asked how the program could support the modelling industry and encourage builder participation.

Two energy modellers' feedback was that the program could increase awareness through targeted marketing efforts, such as utilizing platforms like LinkedIn and organizations such as BOMA.<sup>23</sup> One modeller recommended reducing barriers to entry and simplifying program processes to make participation easier for building owners. One modeller suggested engaging more government clients in the program and fostering connections between builders and energy modellers could help drive participation, especially for large-scale projects with significant energy savings potential. One modeller also suggested increasing the level of incentives and reducing the minimum building size requirement to allow smaller properties to take part.

Four modellers provided suggestions on how E1 could support the building energy modelling industry in Nova Scotia. Suggestions included determining the modelling incentive based on the complexity of the building and promoting Custom New Construction and the benefits of energy modelling among developers. Other suggestions included offering and encouraging training on energy modelling (i.e. workforce development) and providing more opportunity for builders and energy modellers to connect, conducting better outreach to private sector developers, and raising awareness about energy modelling. One modeller did not see a specific role for E1 in supporting the modelling industry.

## 4.6 Market Factors

### 4.6.1 Adoption of NECB 2020

Program participants and non-participating and new energy modellers were asked about the impact of the adoption of the National Energy Code of Canada for Buildings (NECB) 2020 in April 2025 on program participation.

Six of the eight participating builders answered questions about the code change. Two participants believed that, if adopted, NECB 2020 would increase the likelihood of their future participation in Custom New Construction to offset the additional costs associated with increased code requirements. One participant anticipated that the more stringent code would be more difficult to meet, potentially reducing their likelihood of incorporating even higher-efficiency measures thereby limiting their participation in the program. The other three participants said that the changes would not impact their decision to participate, as they already exceed, or intend to exceed, NECB 2020 efficiency requirements.

Two energy modellers interviewed said that as efficiency requirements become more stringent under NECB 2020, builders will likely need to adopt heat pumps and enhance insulation levels to comply. One modeller said stricter requirements could result in more costs and regulatory burdens, possibly discouraging investment in higher-efficiency building upgrades. Another modeller said many builders already prioritize high-efficiency systems, so the impact of NECB 2020 will mainly affect those who have yet to adopt these higher standards.

---

<sup>23</sup> <https://bomacanada.ca/#>

Two of the five modellers have discussed NECB 2020 with their builder clients. These clients expressed concerns about the tight timeline to adjust to the new code, and the difficulty in ensuring code compliance quickly. While some builders may face challenges with timeline and compliance, as noted above, modellers expect many to adopt cost-effective measures like heat pumps to meet NECB 2020 Tier 1 standards, and the impact on those already building with high-efficiency systems may be minimal.

#### 4.6.2 Decarbonization and Electrification

Program participants and non-participating and new energy modellers were also asked about the importance of reducing GHG emissions and the electrification in building design.

Six of the eight participants answered questions about decarbonization and electrification. Five participants mentioned that reducing GHG emissions was very important (n=4) or important (n=1) to their company, while one said it was of little importance. Three participants whose companies value decarbonization said that it influenced their company's participation in Custom New Construction. The commitment of these companies to lowering GHG emissions led them to evaluate the equipment and systems planned for new buildings and identify potential upgrades based on the financial incentives available from E1. For example, one respondent said that the program makes it more financially viable to reduce GHG emissions in the long-term.

Four participants said electrification is either very important (n=2) or important (n=2) to their company, while one believed it is of little importance, and one indicated that it is not at all important. Three of the participants whose company values electrification said that it influenced their participation in Custom New Construction for the potential financial benefits of ensuring upgrades were efficient.

Four modellers have discussed GHG emissions reductions with their builder clients, and four have discussed electrification. When asked what concerns builders might have about GHG emissions reductions and electrification, modellers reported that builders are mostly concerned about high upfront costs and potential financial risks. They also expressed concerns about the adequacy and reliability of electric grid infrastructure, particularly in regions with constrained grids. Additionally, navigating complex and evolving regulations adds to builders' concerns, as does uncertainty about future energy prices and market demand for energy efficient buildings.

Builder concerns cited by energy modellers specific to electrification include longer lead times (n=2), especially for air-to-water heat pumps and equipment using alternatives to the refrigerant R-410A,<sup>24</sup> and the potential unreliability of the utility grid (n=2) as demand increases, or for facilities that require a reliable power source (e.g. hospitals, nursing homes).

### 4.7 Jurisdictional Scan

The evaluator reviewed commercial new construction programs in five jurisdictions and compared them to E1's Custom New Construction service. The jurisdictions and programs reviewed were:

- › BC Hydro/FortisBC (British Columbia) – Clean BC Commercial New Construction
- › NB Power (New Brunswick) – Commercial New Construction
- › Efficiency Manitoba (Manitoba) – New Buildings Program
- › Hydro Québec (Quebec) – Innovative Projects Program
- › Mass Saves (Massachusetts) – Commercial New Construction or Major Renovation Program

---

<sup>24</sup> R-410A is a hydrofluorocarbon (HFC) refrigerant with high global warming potential (GWP). The Canadian government, under the Kigali Agreement, is reducing HFC use 85% by 2036, which compels the HVAC industry to use refrigerants with lower GWP.

A summary of the findings is presented in Table 18 below.

Two key takeaways from the scan are that several jurisdictions researched have no building size requirement or have a lower size requirement than E1, and that while E1's modelling incentive cap is comparable to that of several jurisdictions, the modelling incentive level (as a % of modelling costs) is low compared to some other jurisdictions' (Efficiency Manitoba, National Grid Massachusetts).

Three out of five jurisdictions scanned have adopted NECB 2020, as will Nova Scotia in 2025. Quebec's baseline code is NECB 2015 and Massachusetts' is IECC 2021, which is comparable to NECB 2017. E1's minimum eligibility is 25% better than NECB 2017, which is a lower requirement than New Brunswick Power's requirement of NECB 2020 Tier 3, but higher than Hydro Québec's minimum eligibility of 25% above NECB 2015. A direct comparison to other jurisdictions is difficult because of the differences in baseline code (Efficiency Manitoba) or in the unit of comparison (BC Hydro has a GHG savings minimum).

E1 requires buildings to be larger than 15,000 sq ft, while three jurisdictions have no building size requirement. Hydro Québec focuses on larger facilities, those bigger than 50,000 sq ft. Massachusetts' size requirement varies by path: the New Zero and Low Energy Use Intensity (EUI) Buildings path allows buildings that are 10,000 sq ft or greater, whereas the Whole Buildings EUI Approach path, for larger, complex projects, is for buildings that are 50,000 sq ft or greater.

E1's maximum modelling incentive of \$15,000 is inline with several of the jurisdictions reviewed. It is comparable to BC Hydro's, although BC Hydro pays up to 100% of the costs and E1 pays 50%. Efficiency Manitoba also pays up to 100% of modelling costs, capped at \$12,000. New Brunswick Power offers lower modelling incentives. National Grid Massachusetts offers higher modelling incentives than E1, including a technical assistance incentive of 75%, capped at USD 20,000 (CAD 28,000) plus a 50% verification incentive capped at USD 10,000 (CAD 14,000). Hydro Québec offers up to \$50,000, or \$0.01 per kwh, albeit targeting larger projects.

E1's implementation incentives cannot be directly compared to those of jurisdictions scanned because E1 calculates these on a per kWh saved basis, and other jurisdictions use other structures. BC Hydro bases implementation incentives on GHG savings, and three jurisdictions calculate incentives based on building area. E1's implementation incentive cap of \$750,000 is higher than BC Hydro's (\$500,000) and New Brunswick Power's (\$250,000) but is much lower than Hydro Québec's (\$12,000,000), although Hydro Québec only targets large scale developments and allows multiple buildings to be considered under the same claim.

Also of interest is that two programs, Efficiency Manitoba<sup>25</sup> and National Grid Massachusetts,<sup>26</sup> both have program elements that incentivize operational building performance.

---

<sup>25</sup> As part of Efficiency Manitoba's program's Performance Path, participants must integrate commissioning activities throughout the design and construction phases to verify that building systems are installed and operate according to the intended design specifications. Creating a comprehensive manual detailing the building's systems can also qualify participants for an additional incentive—a 10% bonus on top of the eligible Performance Path incentive amount, up to \$12,000.

<sup>26</sup> A post-occupancy incentive is also available for the National Grid program Path 1: \$2.14 per square foot upon meeting EUI targets after one year of occupancy.

**Table 18: Comparison program of building codes, eligibility, and incentives**

| Jurisdiction                | Equivalent Baseline Code            | Minimum Eligibility (% Better Than Code)                                   | Building Size Requirement                                                                                                                                  | Modelling Incentive                                                                                                                                                                                                              | Implementation Incentive Structure                                   | Maximum Implementation Incentive |
|-----------------------------|-------------------------------------|----------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|----------------------------------|
| Efficiency Nova Scotia      | NECB 2017 (NECB 2020 in 2025)       | 25%                                                                        | >15,000 sq ft                                                                                                                                              | Up to \$15,000, 50% of eligible costs, upon pre-approval                                                                                                                                                                         | \$0.13-\$0.18/kWh                                                    | \$750,000                        |

## 4.8 Logic Model Review

The main objective of the logic model is to link program objectives to barriers and identify actions to address the barriers. The purpose of the logic model review is to assess how well the program's logic and theory of change addresses barriers to achieving program objectives. The Evaluator reviewed the most recent program logic model<sup>28</sup> and underlying theory provided by E1 examining program objectives and barriers. The section concludes with an analysis of how the program logic addresses barriers, and recommendations for updating the logic model and theory of change.

### 4.8.1 Program Objectives

The program objectives stated in the Custom program manual that are most specific to the New Construction service are provided below.

- 1) Influence electrical energy efficiency and system-peak demand reduction projects within Nova Scotia.
- 2) Help BNI customers overcome the barriers to implementing large, complex energy efficiency projects.
- 3) Increase developer and builder awareness of cost-effective options for improving new buildings' energy efficiency.
- 4) Increase the number of new buildings adopting high efficiency design techniques.

The first and fourth objectives are reflected properly in the logic model. However, the second and third objectives are not sufficiently considered. As discussed in more detail below, New Construction does help customers overcome the barriers to implement large and complex new construction projects, but those barriers are not sufficiently presented in the logic model. Awareness-raising activities are in the logic model but these activities are not explicitly tied to a "lack of awareness" barrier.

Further, the long-term outcomes noted in the logic model—develop new program offers, robust custom program, market transformation—are difficult to tie back to program objectives. Within the framework of a logic model and theory of change, outcomes lead to objectives; therefore, the program's logic model and theory should reflect this by showing how outcomes lead to achieving specific objectives.

### 4.8.2 Barriers

Based on interviews with program staff, participating builders, and non-participant and new energy modellers, the evaluator found that high measure costs, modelling costs, and limited developer awareness are the primary barriers to achieving service objectives. Cost and awareness barriers are related. For example, the costs of energy modelling and energy efficiency measures are hard to justify to builders who are not aware of modelling benefits and of energy efficiency measures. Another important barrier is insufficient modeller participation. While E1 has worked to increase the number of participating modellers, according to program staff these modellers do not have enough capacity to support the number of projects coming through the service. Therefore, more participating modellers are needed. These barriers are further described below, followed by a comparison of the barriers presented in the current logic model.

**High costs of energy modelling:** E1 staff reported that the rising cost of energy modelling is a key barrier to achieving service objectives. Modellers also emphasized that the cost of energy modelling, especially for smaller buildings, was the main reason builders decide not to complete an energy model.

---

<sup>27</sup> Program web site unavailable at time of research.

<sup>28</sup> Dated October 28, 2024.

**High measure costs:** E1 staff also said that high upfront costs for efficiency measures is a key barrier, reporting that it can be hard to convince developers to participate when the service can only cover 2% or less of total project costs. Modellers also reported that that high measure costs are also a key barrier to high-efficiency building design. Participating builders worry most about the financial aspects of building high-efficiency buildings and how the costs compare to incentive levels.

**Lack of builder awareness:** Lack of builder awareness of the benefits of building better than code is also a key barrier. E1 staff reported that lack of builder awareness, particularly of long-term cost savings from energy efficient building design, and low familiarity with electric building systems, is a challenge. As noted in Section 4.3, some participant builders have doubts about heat pumps and other measure performance and therefore lack awareness of how well these technologies actually work. Furthermore, the complexity of energy modelling leads to a limited understanding of its value among developers. Modellers also commented that builders may not have a clear understanding of the range of measures and their respective impact on energy efficiency beyond heating systems.

**Insufficient modeller participation:** Insufficient capacity of participating energy modellers was also noted as an issue by program staff. Participating modellers do not have enough time to support all potential service participants. Therefore, another important barrier is an insufficient number of participating modellers.

In the program logic model provided by E1, the barriers to achieving service objectives are:

- 1) Difficulties in meeting program eligibility requirements;
- 2) High incremental cost of energy efficiency measures;
- 3) Lack of technical support in the market for builders to understand efficiency opportunities.

The first stated barrier is a legitimate concern for builders, particularly with respect to the cost of energy modelling, which is required for the service. For clarity, the Evaluator recommends that this barrier be renamed “High energy modelling costs.”

The second barrier was found in the evaluation as noted above. The third barrier is the lack of technical support in the market for builders to understand efficiency opportunities. However, lack of awareness is not directly noted as a barrier. This should be added to the logic model as: “Limited developer awareness of the benefits of energy modelling and high efficiency building design”. Insufficient modeller participation should also be added to the logic model as a barrier.

### 4.8.3 Alignment of Program Logic With Barriers

The service addresses the high costs barrier through financial inputs in the form of modelling and implementation incentives, which result in financial benefits to developers that encourage the construction of energy efficient buildings. Four out of five non-participant and new energy modellers interviewed believed that some builders chose not to complete an energy model for their building primarily because the cost of modelling is too high. E1’s modelling incentives are higher than those offered by New Brunswick Power, but lower than other jurisdictions’ (see Table 18 in Section 4.7); the share of modelling costs covered by E1 (50%), in particular, is low by comparison. Furthermore, 30% of projects reached the modelling cap in 2024, meaning that for 3 out of 10 participants, the modelling incentive will not cover half of their modelling costs.

Some non-participating and new energy modellers suggested higher implementation incentives would further increase participation. It is not clear whether modellers were referring to incentive levels (\$/kWh) or the \$750,000 incentive cap, but there is no direct evidence to support increasing the cap. E1’s cap is already higher than most jurisdictions scanned. Further, analysis of program tracking data shows that the average implementation incentive paid in 2024 was much lower than the cap, and that none of the project incentives reached the cap.

Nevertheless, the shift to NECB 2020 will further increase the cost of high-efficiency buildings, which could prompt a need for E1 to reconsider its incentive structure. One way to do this would be to realign the implementation incentive tiers to reward performance relative to NECB 2020 Tiers 1, 2, and 3. Such incentives would need to evolve as the new code is phased in: Tier 1 will soon be adopted in Nova Scotia in April 2025, followed by Tier 2 in April 2027, and Tier 3 in April 2029.

Limited awareness among developers is also a key barrier, particularly with regard to the long-term cost savings of energy efficient building design and low familiarity with electric building systems. The service addresses the awareness barrier through technical and information service inputs in the form of education, training, and support activities, and human inputs in the form of customer marketing and outreach. Program staff highlighted that the service educates developers and mechanical designers and installers on the benefits of high-efficiency electric technologies. Three participants interviewed said that the performance of energy efficient technologies was a barrier to building high-efficiency buildings, particularly the reliability of equipment given the region's cold climate. The service could help to overcome this barrier by providing evidence to builders to address their lack of awareness on the performance of heat pumps and other measures.

All modellers interviewed said clients are motivated to build energy efficient buildings by the prospect of reducing or controlling their building's operating costs and/or protecting against rising energy costs. Most modellers also reported that their clients complete an energy model to increase the long-term value of their investment through more energy efficient design, and financial implications are the main concern for high-efficiency buildings. E1 reported that program staff meet with new customers early in the design process to discuss the short- and long-term service benefits of energy and cost savings, as well as potential GHG reductions that align with provincial climate targets. The service also educates customers on the benefits of energy modelling, which some developers avoid because they see it as complex or because they do not understand how the costs are justified by the benefits.

Modellers help build a pipeline of participants through relationships with program staff and developers, but there is an insufficient number of energy modellers working with the service. Program staff reported that E1 has positive relationships with participating energy modellers, but that participating modellers currently cannot keep up with market demand. Historically, service participation was limited by the number of participating modellers (most projects were modelled by one modelling firm), but the service has actively recruited energy modellers in recent years (in 2024, five energy modellers participated in the program) and continues to do so. E1 is also considering offering a program training to modellers. E1 reported that the service is actively working to further expand the number of modellers supporting the program, for both MURBs and other building types.

## 4.8.4 Logic Model Summary

To summarize, the evaluator identified four important barriers that the service is working to overcome. These barriers are addressed by and aligned with the program logic model and theory of change to varying degrees. Overall, the service is carrying out activities that address these barriers, though some barriers and related activities are not included in the logic model or theory of change. **Recommended updates to the logic model are specified below.**

- 1) High energy modelling costs: This barrier is not included in the current program logic model or the theory of change. The barrier is addressed by the program through financial inputs in the form of modelling incentives. The logic model and theory of change should be updated to include this barrier.
- 2) High upfront costs of energy efficiency measures: This barrier is included in the logic model and theory of change and is addressed by the service in the form of implementation incentives.
- 3) Limited developer awareness of the benefits of energy modelling and high efficiency building design: This barrier is not explicitly included in the program logic model, though the service carries out multiple awareness raising and educational activities to address a related barrier, “Lack of technical support in the market for builders to understand efficiency opportunities.” The theory of change also notes that the service conducts awareness-raising activities. The program logic model should be updated to include the awareness barrier and ensure program inputs and activities in the logic model and theory of change are aligned with addressing the barrier.
- 4) Insufficient modeller participation is not included in the program logic model, but program staff recognize this barrier and are carrying out service activities to address it (the number of modellers participating has increased in recent years). The theory of change notes that the program tracks the number of energy modellers engaged, and the quality of models submitted. The logic model should be updated accordingly.

## 4.9 Process Evaluation Highlights

Process evaluation highlights are summarized below.

| 2024 Custom NC Process Highlights                                                                                                                                                                                                                                     |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| › There is a relatively high level of participant satisfaction with Custom New Construction overall.                                                                                                                                                                  |
| › The service has been more successful in reaching MURBs than non-MURBs inside the HRM.                                                                                                                                                                               |
| › There are further opportunities for the service to reach outside the HRM, although program eligibility requirements and municipal building rules limit these opportunities to some degree.                                                                          |
| › Participating builders see financial impacts as the main concern when considering building high efficiency buildings.                                                                                                                                               |
| › Builders’ primary concerns about decarbonization and electrification are high upfront costs and financial risks.                                                                                                                                                    |
| › Some builders expressed concerns about the tight timeline to adjust to NECB 2020 and the difficulty in ensuring code compliance quickly.                                                                                                                            |
| › Several jurisdictions scanned have no building size requirement for participation or allow buildings smaller than 15,000 sq ft. Instead of size requirements, two jurisdictions only allow building types specified in NECB 2020 as Part 3 and/or Part 9 buildings. |
| › E1’s incentives for energy modelling, as a share of total modelling costs, are low compared to some jurisdictions.                                                                                                                                                  |
| › High modelling and project costs, lack of developer awareness, and an insufficient number participating modellers were identified as the key barriers to achieving service objectives.                                                                              |
| › Overall, the service is carrying out activities that address these barriers, though some barriers and related activities are not included in the logic model or theory of change.                                                                                   |

## 5 New Construction Impact Evaluation

The objective of the 2024 New Construction impact evaluation was to determine gross and net electrical energy and peak demand savings. In 2024, two types of savings were claimed: (1) partial savings (projects to be completed in future years), and (2) final savings for single-year 2024 projects.

### 5.1 Tracking Sheet Audit

To ensure service results were reliably compiled, the Evaluator first performed a tracking sheet audit intended to verify the completeness and consistency of the data submitted by E1. The verification and corrective actions taken by the Evaluator, where applicable, are described in detail in Appendix XIII. Therefore, the tracked savings results presented in this report refer to the corrected tracked savings obtained by the Evaluator.

### 5.2 Gross Savings

This subsection describes the methodology used by the Evaluator to review the gross savings of New Construction projects.

For New Construction, gross savings for each participating building are calculated using energy models developed with building energy simulation software. Savings are calculated as the difference between the modelled electricity consumption of the baseline and proposed cases. The baseline case corresponds to the reference building as defined in the National Energy Code for Buildings (NECB) Part 8 and the guidelines developed by E1. The proposed case refers to final building design that includes the energy efficiency measures that reduce electricity consumption.

The gross savings evaluation approach for New Construction is conducted through energy model reviews.

#### 5.2.1 Sampling Methodology

For the energy model review, the evaluator selected 12 of the 27 completed projects. The selected sample of 12 projects represented 68% of total tracked energy savings for projects completed in 2024. Only completed projects were considered for sampling, and the one project with partially claimed savings was excluded from the project reviews. This project, an industrial processing facility, will be reviewed in a future evaluation when it is complete (expected in 2025). The Evaluator calculated gross savings by extrapolating the results of the sampled project reviews to all New Construction projects through a weighted average adjustment ratio.

#### 5.2.2 Project Review Findings

The 12 project reviews were intended to validate the energy models developed for the baseline and proposed cases of each project and the resulting savings. The Evaluator based the review mainly on the project files provided by E1. Pictures, mechanical plans, specification sheets, and other documents available in the project files included enough detail to confirm energy efficiency measure installations and validate the input data of the energy models. The most common simulation software remains eQuest; however, compared to previous years, there is more diversity in modelling software being used by participants. In 2024, project models were submitted in IESVE, HAP, Hot2000, and EnergyPlus.

The Evaluator noted one of the 27 completed projects that was modelled in EnergyPlus; however, there was only a calculation file available for this project, and no corresponding visual editor software file. The Evaluator notes that reviewing projects without a visual editor file requires a substantial amount of additional effort. If more projects start being submitted via EnergyPlus models, this issue could hinder the timeliness of future evaluations. **The Evaluator recommends requiring participants to submit visual editor software files when submitting projects modelled in EnergyPlus.** Several visual editing software for EnergyPlus are available for free online, so this requirement should not be a barrier for participant participation.

Of the 12 reviewed projects, 11 were modelled in eQuest and one was modelled in IESVE.

The quality of the information available in the project files continues to be very good. The project files that were provided to the Evaluator were well documented with photos, E1 site visit results, explanatory notes, etc. As a result, no telephone calls to participants were required to complete the 2024 energy model reviews. E1 has implemented a more thorough document tracking procedure to ensure that all files are provided to the Evaluator. This procedure facilitated a much smoother evaluation process compared to previous years. However, for one project, the Evaluator was unable to find the model weather file referenced in the E1 documentation in any online database. **For consistency purposes, the Evaluator recommends that E1 add the model weather file to project documentation as opposed to referencing a file that is stored online.**

There was one project, an industrial facility, for which partial savings were claimed in 2024. This project's building is complete and operational, but the participant is still waiting for an industrial dryer to be installed. The Evaluator worked with E1 to review the calculation approach for this project and determined that the savings generated by the building could be claimed in 2024, while the savings associated with the dryer can be claimed in a future evaluation following commissioning of the equipment. Although not a current program requirement, the Evaluator recommends that E1 staff conduct M&V of the dryer to verify the heating and cooling loads on the building, as well as energy use. The Evaluator will review this project once completed and apply any required corrections to the energy and demand savings that have been claimed in 2024 to future evaluations.

**For future industrial projects, the evaluator recommends adding M&V requirements to section 7.10 of the NC program guide.** The following subsections summarize the adjustments to energy and peak demand savings resulting from the project reviews.

## Energy Savings

Positive or negative adjustments were made to the tracked gross energy savings of all 12 projects reviewed by the Evaluator for 2024.

The energy model reviews resulted in an average adjustment ratio of 1.028 for gross energy savings with a margin of error of 8.3%. The adjustments made were as follows:

- › The most frequent adjustment made was matching the modelled specifications of building systems with the specifications of installed building systems. In many of these cases, the participant building modeller had followed the design specifications. However, upon inspection of the site visit photos, the Evaluator found discrepancies between the as-built and original designs. This type of adjustment was also made several times in the 2023 evaluation; however, the accuracy of as-built models has improved this year thanks to the more diligent document control implemented by E1. Corrections were also made to HVAC and building envelope characteristics.

- 
- › For one project, savings had been claimed prior to the energy recovery ventilators (ERVs) being selected and installed. Savings claimed by E1 were based on the proposed design plans; however, the Evaluator requested that E1 confirm ERV installation with the participant. After reviewing site photos and specifications provided by the participant, the Evaluator found a different ERV to the one originally specified was actually installed in the units. The Evaluator updated the model accordingly, resulting in a downward adjustment to the savings.
  - › Several adjustments were made due to clerical errors in the models, which, upon adjustment by the Evaluator, resulted in savings reductions.

## Peak Demand Savings

In previous evaluations, to establish peak demand savings, the Evaluator extracted the hourly results of the revised building energy model and averaged the monthly peak demand reduction for the months of December, January, and February. For projects modelled in eQuest, which constitute the majority of projects modelled, E1 has been using a script that directly extracts the demand savings from the models. The Evaluator reviewed this script and determined that the savings produced by the script should have been equivalent to those calculated by the previous method (described above) used by the Evaluator. However, minor discrepancies were observed between the results of the two methods. The cause of the discrepancies could not be determined within the timeframe of the evaluation, so for the 2024 evaluation, the Evaluator adopted the method used by E1, using the eQuest script to calculate the evaluated demand savings. **The Evaluator recommends that E1 investigate the cause of the above-mentioned discrepancies and consider updating the demand savings calculation methodology to ensure consistency in calculation methods across the various types of modelling software.**

The differences between tracked peak demand savings and evaluation results were mainly due to the adjustments made to the energy models for energy savings calculations. The average adjustment ratio for gross peak demand savings was 1.003 with a margin of error of 6.9%.

### 5.2.3 Interactive Effects

Since New Construction savings are based on the results of simulation models that model the total electricity consumption of both proposed and reference buildings, interactive effects are already accounted for. No further interactive effects factor was therefore applied to savings.

### 5.2.4 Effective Useful Life

The NC tracking sheet records savings on a measure-by-measure basis for each project. The Evaluator reviewed the EUL values of all measures in the tracking sheet as part of the Tracking Sheet Audit and selected the correct EUL for each measure based on the values outlined in the 2024–2025 DSM Measure Assessment.

## 5.2.5 Evaluated Gross Savings

The 2024 gross energy and peak demand savings calculated for New Construction are presented in Table 19 below. They were obtained by applying the average adjustment ratios of 1.028 on energy savings and 1.003 on peak demand savings for all projects claimed in 2024. To obtain savings at the generator, the line loss factor was applied specifically for each project based on the rate code and corresponding line loss factor provided by NS Power.<sup>29</sup>

**Table 19: Evaluated 2024 New Construction Gross Energy and Peak Demand Savings**

|                                                               | Partial Savings Claimed | Final Savings for Projects Fully Claimed in 2024 | Total          |
|---------------------------------------------------------------|-------------------------|--------------------------------------------------|----------------|
| Number of Projects                                            | 1                       | 27                                               | 28             |
| <b>Energy Savings</b>                                         |                         |                                                  |                |
| Tracked Gross Energy Savings – at the Meter (GWh)             | 6.273                   | 13.340                                           | 19.613         |
| Adjustment Ratio for Energy Savings                           | 1.028                   | 1.028                                            | 1.028          |
| <b>Gross Energy Savings – at the Meter (GWh)</b>              | <b>6.451</b>            | <b>13.720</b>                                    | <b>20.171</b>  |

| Tracked Gross Peak Demand Savings – at the Meter (MW)         | 0.716                   | 3.003                                            | 3.719          |
| Adjustment Ratio for Peak Demand Savings                      | 1.003                   | 1.003                                            | 1.003          |
| <b>Gross Peak Demand Savings – at the Meter (MW)</b>          | <b>0.718</b>            | <b>3.012</b>                                     | <b>3.730</b>   |
| Line Loss Factor                                              | 1.0700                  | 1.0742                                           | 1.0734         |
| <b>Gross Peak Demand Savings – at the Generator (MW)</b>      | <b>0.769</b>            | <b>3.236</b>                                     | <b>4.004</b>   |

As presented in Table 20 below, GHG emission reductions were calculated by applying the Nova Scotia-specific factor<sup>30</sup> for GHG emissions generated by electricity production to New Construction gross savings.

**Table 20: Evaluated 2024 New Construction Gross GHG Emission Reductions**

|                                                                                             | Total         |
|---------------------------------------------------------------------------------------------|---------------|
| <b>Gross Energy Savings – at the Generator (GWh)</b>                                        | <b>21.495</b> |
| Nova Scotia-specific GHG Emissions Factor for Electricity Production (tonnes of CO2 eq/GWh) | 472.2         |
| <b>Gross Annual GHG Emission Reductions (tonnes of CO2 eq)</b>                              | <b>10,150</b> |

<sup>29</sup> Nova Scotia Utility and Review Board, Matter M06555, 2014 Cost of Service Study Progress Update, Exhibit N-2.09, Appendix I1. For municipal utility participants, the line loss factor of the most similar NS Power rate code was assumed.

<sup>30</sup> At the time of writing, 2024 data were not yet available. The Nova Scotia-specific factor was obtained from Nova Scotia Power's 2023 total system emissions data (4,931,152 CO2 eq tonnes), and total electricity generation (10,442 GWh) was drawn from the following two sources: Nova Scotia Power, Total System Emissions, <https://www.nspower.ca/clean-energy/air-emissions-reporting> (last accessed September 27, 2024) and Emera Inc., Emera Inc. 2023 Annual Report, p. 31, available at [https://s25.q4cdn.com/978989322/files/doc\\_financials/2023/ar/Emera\\_2023\\_AR\\_FINAL.pdf](https://s25.q4cdn.com/978989322/files/doc_financials/2023/ar/Emera_2023_AR_FINAL.pdf) (last accessed September 27, 2024).

## 5.3 Net Savings

The NTGR is applied to calculate net savings, that is, the savings that can be reliably attributed to a service. For New Construction, the NTGR was established by considering free-ridership. Spillover was assumed to be zero because a building developer who participated in this program is unlikely to implement energy efficiency measures in other projects without being a repeat participant in the program due to familiarity with the program and the financial incentive to participate, and the 2022 evaluation showed the potential for non-participant spillover is low. Thus, spillover was not measured as part of this evaluation.

### 5.3.1 Free-Ridership

In the case of New Construction, free-ridership occurs when participants would have still implemented energy efficiency measures in their new building in the absence of the service. The free-ridership level was assessed using a self-report approach that involved asking decision-makers a set of questions during phone interviews. The questionnaire used included questions for all applicable variables in the decision-making process, including planning, efficiency, and cost.

To determine free-ridership the Evaluator used a free-ridership questionnaire developed as part of the 2024 evaluation designed to accurately capture all influence factors that can have an impact on building design decisions, such as the energy model, modelling and implementation incentives, as well as technical assistance provided by the energy modeller, BDMS, and New Construction staff. Other factors such as participating organizations' internal energy efficiency policies and market demand for energy efficient buildings were also factored into the calculation.

Certain questions served to determine the extent to which participant decisions to have efficient products installed were influenced by previous participation in an E1 program component or E1 efforts to raise awareness about energy efficiency. When participant answers indicated that they had been significantly influenced by one of these two factors, the free-ridership level was adjusted downward to better capture the overall influence of E1 activities on participant decisions.

The algorithm used to calculate the overall free-ridership level is presented in Appendix XII. The Evaluator attempted to measure free-ridership for the 12 sampled projects in the project review. The Evaluator was able to contact decision-makers for eight of the 12 sampled projects.

The weighted average free-ridership level was measured at 28% with a margin of error of 14.0%, thus representing a decrease compared to the free-ridership level of 31% in 2023. While the margin of error is higher than the standard of 10%, given the small population size, the Evaluator considers this margin of error to be acceptable.

It should be noted that no significant difference was observed in the average free-ridership levels weighted with the energy savings versus peak demand savings. Therefore, the 28% free-ridership level was applied to both total gross energy and peak demand savings.

### 5.3.2 Net-to-gross Ratio Calculation

The NTGR is calculated using the following equation:

$$NTGR = (1 - \% \text{ Free-ridership})$$

Table 21 outlines the free-ridership level established for New Construction along with the calculated NTGR value. Participant spillover is not included as it was assumed to be nil.

**Table 21: Evaluated 2024 New Construction NTGR**

| Projects Fully Claimed in 2024 |             |
|--------------------------------|-------------|
| Free-Ridership Level           | 28%         |
| <b>NTGR</b>                    | <b>0.72</b> |

### 5.3.3 Evaluated Net Savings

Net savings represent the savings that can be reliably attributed to a service. For New Construction, net savings are calculated by applying the NTGR value in the following equation:

$$\text{Net Savings} = \text{Gross Savings} \times \text{NTGR}$$

The results are listed in Table 22 below. The average EUL was established at 19.0 years, and the net energy savings resulted in 7,308 tonnes of CO2 eq in net annual GHG emission reductions.

**Table 22: Evaluated 2024 New Construction Net Energy and Peak Demand Savings**

|                                                             | Partial Savings Claimed | Final Savings for Projects Fully Claimed in 2024 | Total          |
|-------------------------------------------------------------|-------------------------|--------------------------------------------------|----------------|
| <b>Energy Savings</b>                                       |                         |                                                  |                |
| Gross Energy Savings – at the Meter (GWh)                   | 6.451                   | 13.720                                           | 20.171         |
| NTGR                                                        | 0.72                    | 0.72                                             | 0.72           |
| <b>Net Energy Savings – at the Meter (GWh)</b>              | <b>4.645</b>            | <b>9.878</b>                                     | <b>14.523</b>  |
| Line Loss Factor                                            | 1.0631                  | 1.0668                                           | 1.0656         |
| <b>Net Energy Savings – at the Generator (GWh)</b>          | <b>4.938</b>            | <b>10.538</b>                                    | <b>15.476</b>  |
| Effective Useful Life (years)                               | 20.0                    | 18.5                                             | 19.0           |
| <b>Net Lifetime Energy Savings – at the Generator (GWh)</b> | <b>98.735</b>           | <b>195.388</b>                                   | <b>294.123</b> |
| <b>Peak Demand Savings</b>                                  |                         |                                                  |                |
| Gross Peak Demand Savings – at the Meter (MW)               | 0.718                   | 3.012                                            | 3.730          |
| NTGR                                                        | 0.72                    | 0.72                                             | 0.72           |
| <b>Net Peak Demand Savings – at the Meter (MW)</b>          | <b>0.517</b>            | <b>2.169</b>                                     | <b>2.686</b>   |
| Line Loss Factor                                            | 1.0700                  | 1.0742                                           | 1.0734         |
| <b>Net Peak Demand Savings – at the Generator (MW)</b>      | <b>0.553</b>            | <b>2.330</b>                                     | <b>2.883</b>   |

## 5.4 Realization Rate

Table 23 below compares the total 2024 tracked and evaluated savings for New Construction. It also includes the realization rate, representing the ratio of evaluated net savings to tracked net savings, for both energy savings and peak demand savings.

**Table 23: Comparison of 2024 New Construction Tracked and Evaluated Savings at the Generator**

|                       | Gross Savings |      | NTGR  | Net Savings |      | Realization Rate |
|-----------------------|---------------|------|-------|-------------|------|------------------|
|                       | Value         | Unit | Value | Value       | Unit | Value            |
| Energy Savings        |               |      |       |             |      |                  |
| Tracked Savings by E1 | 20.900        | GWh  | 0.72  | 14.421      | GWh  | 107%             |
| Evaluation Results    | 21.495        | GWh  | 0.72  | 15.476      | GWh  |                  |
| Peak Demand Savings   |               |      |       |             |      |                  |
| Tracked Savings by E1 | 3.992         | MW   | 0.72  | 2.754       | MW   | 105%             |
| Evaluation Results    | 4.004         | MW   | 0.72  | 2.883       | MW   |                  |

Evaluated energy and peak demand savings were higher than those tracked by E1 because of adjustments made to the energy models, which resulted in an overall upward adjustment to gross savings. Slightly lower free-ridership in 2024 compared to tracked, also increased the realization rate.

## 6 Building Optimization Impact Evaluation

The objectives of the 2024 Building Optimization impact evaluation were to determine gross and net electrical energy and peak demand savings, annually avoided GHG emissions, as well as EUL values and associated lifetime energy savings. Like Retrofit, Building Optimization includes three types of savings: (1) partial savings (projects to be completed in future years); (2) final savings for single-year projects completed in 2024; and (3) final savings for multiyear projects completed in 2024. In 2024, two single-year projects claimed final savings.

### 6.1 Tracking Sheet Audit

To ensure service results were reliably compiled, the Evaluator first performed a tracking sheet audit aimed at verifying the completeness and consistency of the data submitted by E1. The verification and corrective actions taken by the Evaluator, where applicable, are described in detail in Appendix IV. The tracked savings results presented in this report therefore refer to the corrected tracked savings obtained by the Evaluator.

### 6.2 Gross Savings

Gross savings correspond to changes in energy consumption resulting from actions taken by Building Optimization participants regardless of why they participated. This subsection describes the review methodology used for all Building Optimization projects and the adjustments made to specific projects.

The Evaluator calculated the gross savings for each individual Building Optimization project file in accordance with best measurement and verification practices for commercial and industrial energy efficiency projects. This was achieved by using the information and data made available by participants and E1 as well as by supplementing the data with engineering assumptions and judgments where necessary.

#### 6.2.1 Project Review Findings

The Evaluator reviewed both completed Building Optimization projects. Following the review, the Evaluator revised the energy savings of one project, and the demand savings of both projects.

- › One project involved reprogramming the building HVAC system for 15 separate schools. The energy savings of this project were adjusted slightly upward, because the original energy saving calculation did not capture the full operational schedule of the HVAC systems.
- › The demand savings were adjusted downward for both reviewed projects because the demand saving calculation did not accurately reflect the demand that occurs during the peak demand window.

Since all completed projects were reviewed and adjusted on a case-by-case basis, no average adjustment ratio was established. As such, the Evaluator obtained the total Building Optimization gross energy and peak demand savings by summing the evaluated savings for each project.

Projects that claimed partial savings will have to be reviewed once complete, and any adjustments to the energy savings will be made following individual reviews.

#### 6.2.2 Interactive Effects

Since interactive effects vary significantly from one Building Optimization project to another, they are either accounted for in the project engineering calculations used to establish gross savings or included when using whole building consumption data. For all six projects, the measures implemented did not generate interactive effects. Therefore, no other adjustment was made to the gross savings of reviewed projects.

### 6.2.3 Effective Useful Life

The Evaluator validated the EUL values based on the 2024–2025 DSM MA.

There were no adjustments made to the EUL values of reviewed projects.

### 6.2.4 Evaluated Gross Savings

Table 24 below presents the overall evaluated gross savings for Building Optimization, which were obtained by applying project-specific adjustments to energy and peak demand savings as a result of project reviews. The adjustment ratios in Table 24 are the resulting adjustment ratios for each type of savings claim and are obtained by dividing gross savings without true-up adjustments by tracked savings. The resulting peak demand adjustment ratios were not calculated since peak demand savings were not tracked. However the Evaluator calculated peak demand savings for each Building Optimization project and added them to gross savings. Savings at the generator were calculated using line loss factors that account for electricity losses occurring between the meter and the generator. For each project, the Evaluator applied energy and peak demand line loss factors corresponding to the relevant rate code based on the values drawn from the 2014 Cost of Service Study Progress Update<sup>31</sup> provided by NS Power.<sup>32</sup>

---

<sup>31</sup> Nova Scotia Utility and Review Board, Matter M06555, 2014 Cost of Service Study Progress Update, Exhibit N-2.09, Appendix I1.

<sup>32</sup> For municipal utility participants, the line loss factor of the most similar NS Power rate code was assumed.

| <p>*The adjustment ratios listed in this table are the averages obtained by dividing gross energy savings without true-up adjustments by tracked gross energy savings.</p> <p>**The line loss factors are average values obtained by dividing gross savings at the generator by gross savings at the meter. Each Retrofit project received its own specific line loss factor depending on participant rate codes.</p> <p>***These are average EUL values obtained by dividing gross lifetime energy savings by gross energy savings. Each retrofit project received its own specific EUL to obtain lifetime savings.</p> |                         |                                                |              |

As presented in Table 25 below, GHG emission reductions were calculated by applying the Nova Scotia-specific factor<sup>33</sup> for GHG emissions generated by electricity production to Building Optimization gross savings.

<sup>33</sup> At the time of writing, 2024 data were not yet available. The Nova Scotia-specific factor was obtained from Nova Scotia Power's 2023 total system emissions data (4,931,152 CO<sub>2</sub> eq tonnes), and total electricity generation (10,442 GWh) was drawn from the following two sources: Nova Scotia Power, Total System Emissions, <https://www.nspower.ca/clean-energy/air-emissions-reporting> (last accessed September 27, 2024) and Emera Inc., Emera Inc. 2023 Annual Report, p. 31, available at [https://s25.q4cdn.com/978989322/files/doc\\_financials/2023/ar/Emera\\_2023\\_AR\\_FINAL.pdf](https://s25.q4cdn.com/978989322/files/doc_financials/2023/ar/Emera_2023_AR_FINAL.pdf) (last accessed September 27, 2024).

**Table 25: Evaluated 2024 Building Optimization Gross GHG Emission Reductions**

|---------------------------------------------------------------------------------------------|-------|
| Gross Energy Savings – at the Generator (GWh)                                               | 1.975 |
| Nova Scotia-specific GHG Emissions Factor for Electricity Production (tonnes of CO2 eq/GWh) | 472.2 |
| Gross Annual GHG Emission Reductions (tonnes of CO2 eq)                                     | 933   |

## 6.3 Net Savings

The Evaluator determined the net energy and peak demand savings, that is, the electrical energy and peak demand savings that can be reliably attributed to a service, by estimating the NTGR. For Building Optimization, free-ridership and spillover are accounted for in the NTGR calculation.

Given the smaller contribution of Building Optimization to Custom savings, free-ridership and spillover levels were not measured in 2024. To obtain net energy and peak demand savings, the Evaluator applied the NTGR results from the 2021 Custom evaluation to gross savings.

### 6.3.1 Net-to-gross Ratio Calculation

The NTGR was calculated using the following equation:

$$NTGR = (1 - \% \text{ Free-ridership} + \% \text{ Participant Spillover})$$

Table 26 outlines the free-ridership and spillover levels established for Building Optimization along with the NTGR value.

**Table 26: Evaluated 2024 Building Optimization NTGR**

|                                                                                                                       | Value for Savings Claimed in 2024 * |
|-----------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| Free-Ridership Level                                                                                                  | 9% (±7.2%)                          |
| Participant Spillover Level                                                                                           | 0%                                  |
| <b>NTGR</b>                                                                                                           | <b>0.91</b>                         |
| *Free-ridership and spillover levels were not measured in 2024, results from the 2021 Custom evaluation were applied. |                                     |

### 6.3.2 Evaluated Net Savings

Net savings represent the savings that can be reliably attributed to a service. For Building Optimization, net savings are calculated by applying the NTGR value in the following equation:

$$\text{Net Savings} = \text{Gross Savings} \times \text{NTGR}$$

The detailed net savings results are presented in Table 27. The average EUL was established at 7.9 years, and the net energy savings resulted in 311 tonnes of CO2 eq in net annual GHG emission reductions.

**Table 27: Evaluated 2024 Building Optimization Net Energy and Peak Demand Savings**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Partial Savings Claimed | Final Savings Claimed for Single-Year Projects | Total        |

| <p>*The line loss factors are average values obtained by dividing gross savings at the generator by gross savings at the meter. Each Retrofit project received its own specific line loss factor depending on participant rate codes.</p> <p>**These EULs are average EUL values obtained by dividing Gross Lifetime Energy Savings by Gross Energy Savings. Each Retrofit project received its own specific EUL to obtain lifetime savings.</p> |                         |                                                |              |

## 6.4 Realization Rate

A comparison of the energy and peak demand savings values established through this evaluation and those tracked by E1 is presented in Table 28 below. It also includes the realization rate, representing the ratio of evaluated net savings to tracked net savings, for both energy savings and peak demand savings.

**Table 28: Comparison of 2024 Building Optimization Tracked and Evaluated Savings at the Generator**

|                       | Gross Savings |      | NTGR  | Net Savings |      | Realization Rate |
|-----------------------|---------------|------|-------|-------------|------|------------------|
|                       | Value         | Unit | Value | Value       | Unit | Value            |
| Energy Savings        |               |      |       |             |      |                  |

| Evaluation Results    | 1.975         | GWh  | 0.91  | 1.797       | GWh  |                  |
|                       |               |      |       |             |      |                  |
| Tracked Savings by E1 | 0.102         | MW   | 0.91  | 0.093       | MW   | 90%              |
| Evaluation Results    | 0.092         | MW   | 0.91  | 0.083       | MW   |                  |

Evaluated energy savings were higher than those tracked by E1 due to a slight upward adjustment made to the energy savings for one project. Evaluated peak demand savings were lower than those tracked by E1 due to the correction made to the peak demand savings methodology.

## 7 Overall Savings for Custom

A comparison of the energy and peak demand savings values established through this evaluation and those tracked by E1 is presented in Table 29. The realization rate, representing the ratio of evaluated net savings to tracked net savings, was established at 108% for energy savings and at 105% for peak demand savings.

**Table 29: Comparison of 2024 Custom Tracked and Evaluated Savings at the Generator**

|                                                                                                                                                 |                       | Gross Savings |      | NTGR* | Net Savings |       | Realization Rate |
|-------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|---------------|------|-------|-------------|-------|------------------|
|                                                                                                                                                 |                       | Value         | Unit | Value | Value       | Value | Unit             |
| Retrofit                                                                                                                                        | Energy Savings        |               |      |       |             |       |                  |
|                                                                                                                                                 | Tracked Savings by E1 | 26.115        | GWh  | 0.79  | 20.719      | GWh   | 109%             |
|                                                                                                                                                 | Evaluation Results    | 26.355        | GWh  | 0.86  | 22.677      | GWh   |                  |
|                                                                                                                                                 | Peak Demand Savings   |               |      |       |             |       |                  |
|                                                                                                                                                 | Tracked Savings by E1 | 2.688         | MW   | 0.81  | 2.169       | MW    | 106%             |
|                                                                                                                                                 | Evaluation Results    | 2.691         | MW   | 0.85  | 2.289       | MW    |                  |
| New Construction                                                                                                                                | Energy Savings        |               |      |       |             |       |                  |
|                                                                                                                                                 | Tracked Savings by E1 | 20.900        | GWh  | 0.69  | 14.421      | GWh   | 107%             |
|                                                                                                                                                 | Evaluation Results    | 21.495        | GWh  | 0.72  | 15.476      | GWh   |                  |
|                                                                                                                                                 | Peak Demand Savings   |               |      |       |             |       |                  |
|                                                                                                                                                 | Tracked Savings by E1 | 3.992         | MW   | 0.69  | 2.754       | MW    | 105%             |

|                                                                                                                                                 | Tracked Savings by E1 | 6.782         | MW   | 0.71  | 5.017       | MW    | 105%             |
|                                                                                                                                                 | Evaluation Results    | 6.774         | MW   | 0.79  | 5.255       | MW    |                  |
| * NTGRs differ for each service. The NTGRs listed in this table match the rounded averages obtained from dividing net savings by gross savings. |                       |               |      |       |             |       |                  |

As outlined in Figure 9 below, Custom surpassed its electrical energy savings target by 48% and its peak demand savings target by 29%. Custom achieved 628.964 GWh and 486.215 GWh in gross and net lifetime electrical energy savings respectively, resulting in a weighted average EUL of 12.6 years for gross electrical energy savings and 12.2 for net electrical energy savings. The reason evaluated electrical energy and peak demand savings were much higher than the targets was likely due to partial claims made in 2024 after the targets had been set. Two compressed air leak Retrofit projects and one New Construction project with partial claims in 2024 accounted for 13.560 GWh of evaluated electrical energy savings.

**Figure 9: 2024 Custom Targets and Evaluated Results**

## 8 Custom Key Findings and Recommendations

The main objectives of the 2024 Custom evaluation were as follows:

- › Calculate gross and net results, namely electrical first-year and lifetime energy savings, peak demand savings, as well as avoided GHG emissions.
- › Collect information on participant and non-participant perspectives for New Construction.
- › Collect information on participation motivations, barriers, and the decision-making process for New Construction.

This section provides the Evaluator's key findings and recommendations in relation to these objectives. The first key findings and recommendations apply to Custom in general, while the others are specific to certain Custom services. The recommendations are also outlined in Appendix XIV.

### General Custom Key Findings and Recommendations

#### **2024 Custom-Finding: Custom net electrical energy and peak demand savings surpassed targets in 2024.**

Custom achieved 39.951 GWh in net electrical energy savings and 5.225 MW in net peak demand savings at the generator in 2024, thereby surpassing the planned electrical energy savings of 27.036 GWh by 48% and the planned peak demand savings of 4.101 MW by 28%.

#### **2024 Custom-Finding: Compared to 2023, Custom participation decreased in 2024.**

With 104 projects completed across the four Custom services,<sup>34</sup> the 2024 participation level for Custom was lower than 2023 with 114 completed projects. The number of completed projects decreased from 93 in 2023 to 75 in 2024 for Retrofit, and it decreased from 6 in 2023 to 2 in 2024 for Building Optimization. New Construction saw a large increase in participation in 2024, with 27 projects completed compared to 15 in 2023.

#### **2024 Custom-Finding: Following the project reviews, the Evaluator adjusted the energy and peak demand savings for Retrofit, New Construction, and Building Optimization.**

For Retrofit, the Evaluator adjusted energy or peak demand savings, which varied for each project category (regular Retrofit, solar PV, and compressed air leak audit projects). These adjustments resulted in an adjustment ratio of 1.012 for energy savings and 1.002 for peak demand savings.

For Building Optimization, the Evaluator adjusted the energy savings of one project and the demand savings of both reviewed projects, resulting in an adjustment ratio of 1.068 for electrical energy savings and 0.899 for peak demand savings.

For New Construction, resulting adjustment ratios for gross energy and peak demand savings were 1.028 and 1.003 respectively.

---

<sup>34</sup> Custom includes four services: Retrofit (75 projects completed), New Construction (27 projects completed), Pay-for-Performance (no projects completed), and Building Optimization (two projects completed).

**2024 Custom-Finding: Retrofit free-ridership level decreased for regular Retrofit projects. New Construction free-ridership decreased slightly compared to the 2023 level.**

The overall free-ridership level for regular Retrofit projects was established at 15%. Free-ridership levels were not measured for compressed air leak audit and solar PV projects, and were therefore maintained at 38% (value from 2023) and 16% (value from 2021), respectively. Free-ridership was not measured for Building Optimization and was maintained at 9% (value from 2021).

The 2024 free-ridership level for New Construction was established at 28%, down from 31% in 2023.

Retrofit spillover was established at nil for regular Retrofit projects. Spillover was not measured for Building Optimization and therefore maintained as nil (value from 2021).

**2024 Custom-Finding: Both the evaluated net energy and peak demand savings determined by the Evaluator were higher than the savings tracked by E1.**

Evaluated net energy and peak demand savings were 8% and 5% higher than the values tracked by E1.

## **New Construction Key Findings and Recommendations**

**2024 New Construction-Finding: The demand savings calculation approach used by E1 for projects modelled in eQuest can generate results that are difficult to confirm.**

The Evaluator found minor discrepancies in demand savings when comparing results of the modelling approach used by the Evaluator to those resulting from E1's approach for projects modelled in eQuest. The approach used by E1 involves running a script directly in the eQuest modelling software, an approach not applied to projects modelled using other software.

**2024 New Construction Recommendation #1:** Review the demand savings script used for projects modelled in eQuest to ensure accurate results and favour an approach that can be applied consistently across a variety of modelling software.

**2024 New Construction-Finding: E1 expects a large industrial New Construction project to be closed in 2025.**

The Evaluator reviewed the proposed calculation methodology for this industrial project and determined that savings could be claimed for the building portion of the project prior to the final pieces of industrial equipment being installed. To support the agreed upon calculation methodology, E1 staff will conduct M&V to confirm the heat load added to the building by the installed equipment. The whole project will be evaluated following final installation of the equipment.

**2024 New Construction Recommendation #2:** Amend section 7.10 of the New Construction program guide to require M&V for large industrial New Construction projects.

**2024 New Construction-Finding: The share of completed projects supported by the service that are MURBs has increased in recent years, consistent with the growth of the MURB market inside the HRM.**

MURBs have comprised the majority of New Construction projects since 2022, and MURBs made up 24 of the 27 completed projects in 2024. Analysis of HRM building permits suggests that this participation trend generally follows the growing size of the MURB market, though there may be further opportunities to capture more non-MURB buildings, the market for which has also grown.

**New Construction-Finding: The service has a higher portion of projects inside the HRM, which is to be expected. Targeting a higher number of buildings outside the HRM may require a change in building size eligibility criteria.**

The HRM contains about half of the province's population, so a higher proportion of projects inside the HRM is expected given the density of the population in the city. In addition, building rules inside the HRM streamline permitting processes and encourage larger and faster-built buildings, whereas conditions outside the HRM are less favourable for larger buildings. The jurisdictional scan found some programs with smaller building size requirements (i.e. aligned with NECB 2020 Part 9 buildings); such an approach could be considered by E1 if the program wishes to capture a higher proportion of projects outside the HRM.

**2024 New Construction-Finding: Participants are satisfied with the program overall, particularly in terms of E1's responsiveness, and are moderately satisfied with the value of the program for their business.**

E1's responsiveness and speed of application approval received the highest satisfaction ratings. Participants reported lower satisfaction on elements related to the value of the program given the time and costs requirements for builders, and the ability to estimate a return on investment associated with the program.

**2024 New Construction-Finding: Non-participant modellers are aware of and somewhat familiar with New Construction service, including those that work on non-MURB projects.**

All three non-participant modellers interviewed work on buildings that would be eligible for New Construction (i.e. electrically heated and 15,000 square feet or larger). Only one of the three non-participant modellers said they had discussed the service with their clients.

**2024 New Construction-Finding: Decarbonization is a motivator for participating in New Construction service.**

Almost all participants answering questions about decarbonization (five out of six) reported that GHG emissions were important to their company and three said that it motivated them to participate in the service.

**2024 New Construction-Finding: Financial factors are the primary barriers for energy efficient new construction projects (higher costs of energy efficient measures, cost of energy modelling), as well as builder awareness and understanding of the benefits of energy efficient construction, and insufficient modeller participation in the service.**

These barriers appear to be consistent across both MURB and non-MURB markets.

**2024 New Construction-Finding: The share of modelling costs covered by the program's modelling incentive may be insufficient to motivate some builders.**

Both staff and modellers noted that modelling costs are increasing and that these costs can be a barrier, notably for smaller eligible projects. Further, 30% of projects hit the modelling cap in 2024, implying that for 3 out of 10 participants, the modelling incentive is not covering half their modelling costs. The jurisdictional scan indicated that several jurisdictions have higher modelling incentive offers (either in portion of costs covered or cap) than E1.

**New Construction Recommendation #3:** Investigate the impact of increasing modelling incentives (the share of modelling costs covered as well as the incentive cap) on the service.

**2024 New Construction-Finding: The program component would benefit from additional supporting energy modellers.**

Historically one energy modeller supported most of the New Construction service projects. E1 has worked to bring in more modellers to the program and in 2024, five energy modellers participated in the program. Further efforts should be taken to ensure a diverse group of modellers are aware of and engaged in the program.

**New Construction Recommendation #4:** Endeavour to recruit new energy modellers through targeted outreach; modellers put a premium on networking opportunities with builders.

**New Construction Recommendation #5:** Consider collaborating with educational institutions and professional associations for energy modelling to build a stronger pipeline of qualified and engaged energy modellers across Nova Scotia.

**2024 New Construction-Finding: The service should prepare for the shift to NECB 2020 in Nova Scotia. Builders will need to adjust designs, plan for higher efficiency technologies and higher upfront costs, and work closely with energy modellers under the new code.**

Nova Scotia will phase in Tiers 1, 2, and 3 of NECB 2020 over 2025–2029. The jurisdictional scan noted three programs that have aligned with NECB 2020 code adopted in their province. Participants and modellers are mixed in terms of how the code could impact program participation. Three jurisdictions scanned (BC Hydro, New Brunswick Power, and Efficiency Manitoba) all do this.

**New Construction Recommendation #6:** The program should increase targeted outreach and educational activities for builders and energy modellers related to the code shift and its impacts, particularly those involving technologies (including electrification), costs, and energy efficiency improvements. By providing practical guidance on meeting new requirements and exceeding them with the program's support, the program can position itself as a valuable resource while increasing program awareness and encouraging more participation.

**New Construction Recommendation #7:** Review the program guidelines and update to align with NECB 2020, which will be adopted in April 2025.

**New Construction Recommendation #8:** Investigate aligning implementation incentives with NECB 2020 Tiers. Such alignment would need to consider the phased-in adoption of NECB 2020 Tiers 1–3 over 2025–29.

**2024 New Construction-Finding:** The logic model is out of date and does not sufficiently document the program barriers or the activities currently being undertaken by the program to address these barriers.

The Evaluator found that the program's activities are aligned with the barriers identified in the evaluation. However, the logic model and theory of change do not reflect this and needs to be updated to capture the reality of the market barriers and program activities today.

**New Construction Recommendation #9:** E1 should update the Custom New Construction logic model to document and address current barriers and update the theory of change to include all activities being carried out to address these barriers.

## 9 SEM Overview

This section describes the Strategic Energy Management (SEM) program component, follows up on past evaluation recommendations, and provides an overview of participation history.

### 9.1 SEM Description

SEM provides industrial and institutional participants with funding and support to implement energy management practices within their organizations. It also provides participants with energy management information system (EMIS) implementation support.

SEM helps participants achieve continuous energy savings by offering a structured approach to identifying, prioritizing, and completing energy-saving actions through the implementation of energy management policies and processes. To be eligible, participants must possess the necessary resources to implement energy efficient improvements, demonstrate commitment to energy management, and identify committed personnel to work in collaboration with E1 throughout the duration of projects.<sup>35</sup> Activities are conducted through a third-party Service Provider that delivers the program component. Participants commit to participating for 12 months, although E1 offers additional years to participants who want to continue operating the energy management system. SEM participants can also obtain funding for an EMIS, which is an additional tool that assists participants in using energy consumption data from metered systems to inform decisions about their processes. This funding may be used to conduct an EMIS audit, develop and implement an EMIS plan that involves the configuration of metering and monitoring equipment, as well as procure training and organizational support.

SEM provides participants with energy Kaizens<sup>36</sup> and mapping, treasure hunts,<sup>37</sup> energy management assessments, as well as performance monitoring and reporting tools. SEM also provides employee training and organizational support for the implementation of energy management engagement activities that use energy performance information to prompt actions aimed at achieving behavioural change and operation and maintenance related energy-saving measures. Ultimately, SEM helps develop an energy management plan focused on changing business practices to enhance long-term energy performance.

Figure 10 below illustrates the SEM participation process along with details about the program component.

---

<sup>35</sup> An SEM project is defined as the implementation of a strategic energy management system in a facility.

<sup>36</sup> Energy Kaizens are activities aimed at continuously improving energy consumption by identifying waste and focusing on eliminating it.

<sup>37</sup> These consist of walkthroughs of plants aimed at identifying energy-saving opportunities.

**Figure 10: 2024 SEM Participation Process Summary**

Starting in 2021, SEM participants have been offered performance-based incentives for the savings achieved through the program component. The objectives of this incentive are to facilitate recruitment and encourage the completion of energy efficiency projects. SEM participants may enroll in the Large Industrial initiative aimed at filling energy management capacity gaps for large industrial customers; as such, they receive additional support in the form of a dedicated industrial energy manager (IEM), and the savings they achieve through SEM are incentivized at \$0.06/kWh. SEM participants who are not part of the Large Industrial initiative also receive a performance-based incentive although at a lower rate of \$0.04/kWh.

SEM was aimed at generating net electrical energy savings of 4.222 GWh and peak demand savings of 0.470 MW at the generator in 2024.

## 9.2 Follow-up on Past Evaluation Report Recommendations

The Evaluator evaluated SEM in previous years and issued improvement recommendations. Table 30 provides a summary of the implementation status of the recommendations presented in the Executive Summary section of the 2023 SEM Evaluation Report.

**Table 30: Implementation Status of Past Recommendations for SEM**

| #           | Recommendations                                                                                                                                                   | Status      | Comments                                                                                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2023-SEM-R1 | Consider including plant-level key performance indicators (KPIs) and tracking their progression since program component inception in participant reporting.       | In progress | In 2024, E1 program staff worked with the SEM service provider to determine which plant-level KPIs to include in participant reporting. In 2025, E1 staff will continue to work with the SEM service provider to determine and implement plant-level KPIs in participant reporting.                                                                    |
| 2023-SEM-R2 | Track the number of projects implemented by SEM participants and the resulting savings from capital projects incented in Business Energy Rebates (BER) or Custom. | Complete    | In 2024, E1 program staff tracked projects implemented by Strategic Energy Management (SEM) participants and detailed the resulting savings from capital projects incented in BER or Custom. Details on projects, savings, and incentives were provided in the final SEM tracking sheet submitted for the 2024 evaluation process.                     |
| 2023-SEM-R3 | Better communicate the value of energy management to both participants and non-participants, including its decarbonization potential.                             | In progress | In 2024, E1 program staff worked with other departments to ensure messaging on decarbonization was clear and that participants fully understood all of the benefits associated with SEM. In addition, program staff discussed this recommendation with the SEM Service Provider that subsequently added this topic to their regular customer meetings. |

## 9.3 Participation History

There were 12 active participants in SEM in 2024, nine continuing participants and three new participants. Moreover, seven of the 12 active participants achieved savings in 2024. The electrical energy savings level was at its highest since program inception in 2015, slightly above 2023 results; this can be attributed to two participants who in total contributed 69% of total electrical energy savings. Figure 11 and Figure 12 below illustrate the participation and savings trends since 2018 respectively.

Figure 11: Overview of SEM Participation, 2018-2024<sup>38</sup>

Figure 12: Evolution of SEM Gross Savings, 2018-2024

Similarly to 2023, most SEM electrical energy savings are the result of compressed air leak repair measures as illustrated in Figure 13 below. Of the 21 measures implemented by participants in 2024, five were compressed air leak repairs, 53% of which contributed to 2024 electrical energy savings.

<sup>38</sup> The 2019 savings values per participant are based only on the savings that occurred in 2019. In this graph and the following, EMIS savings were included in historical data – they are presented in green.

Figure 13: Distribution of 2024 SEM Energy Savings per Measure Category

## 10 SEM Evaluation Approach

The 2024 SEM evaluation comprised a comprehensive impact evaluation. The main objectives of the SEM evaluation were as follows:

- › Calculate SEM gross and net results, namely electrical first-year and lifetime energy savings, peak demand savings, and avoided GHG emissions.

The Evaluator identified key research questions aimed at achieving these objectives. Table 31 outlines the evaluation objectives and maps them to the Evaluator's research questions, methods, and sample sizes (n). Each method is described further below.

**Table 31: 2024 SEM Evaluation Approach**

| Evaluation Objectives   | Research Questions                                                                                                                                                                                                                                                                                                                                                             | Methodology                                                                                                                                                                                               |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Calculate gross results | <ul style="list-style-type: none"><li>› Are the data in the tracking sheet complete, accurate, and consistent?</li><li>› Are the gross savings for each project accurately calculated?</li><li>› Have the correct EUL values been applied to each measure?</li><li>› What are the evaluated first-year and lifetime gross electrical energy and peak demand savings?</li></ul> | <ul style="list-style-type: none"><li>› Tracking sheet audit</li><li>› Project file reviews with participant follow-up interviews or site visit</li><li>› Calculations using evaluation results</li></ul> |

### Tracking Sheet Audit

Prior to performing the savings review, the Evaluator audited the final 2024 tracking sheet to ensure it was complete and data entry was consistent. The detailed protocol used for the tracking sheet audit and the results obtained are presented in Appendix XV.

### Project File Reviews

In January 2024, a total of seven project reviews were conducted, one for each participant that generated savings. Of these project reviews, three were supported by phone interviews, while site visits were conducted for one other participant – the other projects did not require clarifications from participants; therefore, no interview was needed. The desk reviews and phone interviews were conducted by Econoler. Equilibrium Engineering conducted one site visit for the only new participant that generated savings in 2024; the participant questions and equipment visited during that visit were guided by the results of the project review performed by the Evaluator ahead of the visit. The Evaluator also contacted the Service Provider for clarifications where necessary.

The protocol used to conduct the interviews and project reviews is presented in Appendix XVI, while detailed project review adjustments are provided in Appendix XVI.

### Calculations Using Evaluation Results

Building on all the above methods and collected data, the Evaluator calculated the first-year and lifetime gross energy and peak demand savings as per the calculation methodology presented in Section 11 below.

## GHG Emission Reduction Calculations

To obtain net avoided GHG emissions in CO<sub>2</sub> eq for SEM, the Evaluator multiplied the net energy savings by the latest Nova Scotia-specific factor for GHG emissions generated by electricity production. This factor was established using Nova Scotia Power (NS Power) data.

## 11 SEM Impact Evaluation

The objectives of the 2024 SEM comprehensive impact evaluation were to determine project gross and net electrical energy and peak demand savings as well as annually avoided GHG emissions, EUL values, and associated lifetime electrical energy savings.

### 11.1 Tracking Sheet Audit

To ensure program component results were reliably compiled, the Evaluator first performed a tracking sheet audit aimed at verifying the completeness and consistency of the data submitted by E1. The results obtained from the tracking sheet audit are presented in Appendix XV. The tracked savings results presented in this report therefore refer to the corrected tracked savings obtained by the Evaluator.

### 11.2 Gross Savings

For SEM, gross savings correspond to the change in energy consumption resulting from actions taken by participants regardless of their reasons for participating.<sup>39</sup> The subsections below provide a description of the methodology used to review the seven SEM projects that generated savings in 2024 and a summary of the review findings. Interactive effects, EUL values, and revised gross electrical savings were also assessed.

#### 11.2.1 Project Review Findings

The Evaluator reviewed the calculation methodologies for the seven projects based on project documentation and information from interviews with participants and the Service Provider. All but two projects used a bottom-up approach to quantifying savings by applying a distinct M&V methodology for each measure, which is consistent with how Custom Retrofit savings are typically measured. While the bottom-up approach to quantifying savings has been the preferred approach since 2022, a top-down approach is appropriate in cases where a measure impacts the entire facility, making interactive effects difficult to quantify or when monitoring individual components is not feasible. In these cases, savings are determined by continuously measuring the energy consumption and demand at the whole facility level during the reporting period. The Service Provider selected a bottom-up or top-down approach in a manner that is consistent with the M&V procedure developed by the Service Provider and approved by the Evaluator.

The M&V reports for each measure were complete and provided a clear understanding of the measures and the savings quantification approach. In nearly all cases, the Evaluator found the overall M&V methodology to be thorough and in alignment with best practices, including the usage of pre- and post-measurements at the measure level (in the case of bottom-up approaches) or at the facility level (in the case of top-down approaches). For compressed air measures specifically, the M&V approach applied by participants involved measuring the airflow of each leak using an ultrasound leak detector and validating that the leak was no longer detectable after the repair. As part of the review, the Evaluator ensured that no leaks were reported twice and that the conversion from cubic feet per minute of compressed air to kW was performed using a conservative compressor efficiency if no compressor efficiency measurement specific to the given facility was available. No adjustments were made to the electrical energy or peak demand savings of any compressed air leak projects since they all followed this methodology correctly.

---

<sup>39</sup> Definition adapted from National Renewable Energy Laboratory, The Uniform Methods Project Chapter 23: Estimating Net Savings: Common Practices, September 2014, p. 3.

The exception to M&V being aligned with best practices was the calculation of peak demand savings for the two projects that used a top-down approach to measure savings. In these cases, the Evaluator concluded that dividing the energy savings by the total number of hours in the year (i.e. 8,760 hrs) produced a conservative estimate of peak demand savings. For one of these projects, it was found that, by analyzing the hourly interval data to determine peak demand savings, the Evaluator was able to increase the savings by a factor of three.

The Evaluator made a few adjustments to electrical energy and peak demand savings in addition to a change in methodology for the top-down peak demand savings calculation. The Evaluator adjusted electrical energy savings for three measures across two separate projects. For one project, a calculation error in the spreadsheet led to a 0.5% decrease in measure electrical energy savings. A second measure in the same project was updated due to an overestimation of operating hours, resulting in an 8.5% decrease in measure electrical energy savings. The second project, to which a top-down M&V approach was applied, underestimated the electrical energy savings from a non-routine adjustment relating to a new pump installation. This adjustment resulted in a 0.1% decrease in project electrical energy savings.

The Evaluator also adjusted the peak demand savings claimed for four projects, with three downward and one upward adjustment. One project had adjustments made to account for how data was processed in a spreadsheet, which resulted from the use of an extra interval of energy data in the calculations. For this project, peak demand savings were decreased by 3% from 54.4 kW to 53.0 kW. In another project, an operational change in how scrap material was reintroduced led to decreased energy consumption on the weekends and a slight increase in peak demand during the week. This resulted in a downward adjustment to peak demand savings from 0 kW to -1.2 kW as the measure led to an overall increase to demand during the peak coincident period. Another downward adjustment was made to the peak demand savings for two vacuum pump sequencing measures. In both cases, the interval data was not collected during the winter peak months of December to February. Although the peak demand savings calculated included data from peak hours between 5 p.m. to 7 p.m., the data included values collected from holidays and weekends. Since the collected interval data was limited and did not align with the coincident peak hours, the Evaluator updated the peak demand savings to ensure the estimated savings were conservative. In this case, assuming a peak coincidence factor of 1 resulted in an 18% decrease in peak demand savings for the project. The last adjustment resulted in a 301% increase to peak demand savings. In this project, an operational change allowed for two molding machine lines to be decommissioned. The Evaluator based this adjustment on facility hourly interval data for the coincident peak demand period during the reporting period as opposed to using an engineering calculation to estimate savings.

Overall, the adjustment ratios for both the gross and net electrical energy and peak demand savings were 1.000 and 1.002 respectively.

### 11.2.2 Interactive Effects

For each project reviewed, the Evaluator validated if interactive effects should have been considered and concluded that no interactive effects impacted the concerned measures. Hence, no additional interactive effects were applied to measured savings.

### 11.2.3 Effective Useful Life

As part of the 2024-2025 Demand-side Management Measure Assessment (DSM MA)<sup>40</sup> activities, the Evaluator reviewed the EUL values for all measure categories to ensure they were still valid and revised them where appropriate. For all projects, the Evaluator estimated the proportion of savings achieved by measure and assigned a measure-specific EUL in accordance with the EUL values found in the 2024-2025 DSM MA. This resulted in a weighted average EUL of 2.6 years.

### 11.2.4 Evaluated Gross Savings

The 2024 evaluated SEM gross energy and peak demand savings at the generator are listed in Table 32 below.

The gross energy and peak demand savings at the generator were estimated by using different line loss factors between the meter and the generator for energy and peak demand savings based on each facility rate code and line loss factor values drawn from the 2014 Cost of Service Study Progress Update.<sup>41</sup>

**Table 32: Evaluated 2024 SEM Gross Electrical Energy and Peak Demand Savings**

|                                                               | New Projects | Continuing Projects | Total         |
|---------------------------------------------------------------|--------------|---------------------|---------------|

| <b>Gross Peak Demand Savings – at the Generator (MW)</b>      | <b>0.143</b> | <b>0.395</b>        | <b>0.538</b>  |

As presented in Table 33, GHG emission reductions were calculated by applying the Nova Scotia-specific factor<sup>42</sup> for GHG emissions generated by electricity production to SEM gross savings.

<sup>40</sup> The 2024-2025 DSM MA is a reference document that provides an in-depth review of all parameters necessary to calculate the annual and lifetime gross energy and peak demand savings of most prescriptive measures and some semi-prescriptive measures offered through EfficiencyOne's DSM program portfolio. In addition, the Measure Assessment includes effective useful life values for all measures offered in E1's program portfolio. For the remainder of the evaluations to be conducted during the 2023-2025 DSM cycle, the Evaluator will refer to the values presented in the 2024-2025 DSM MA

<sup>41</sup> Nova Scotia Utility and Review Board, Matter M06555, 2014 Cost of Service Study Progress Update, Exhibit N-2.09, Appendix I1. For municipal utility participants, the line loss factor of the most similar NS Power rate code was assumed.

<sup>42</sup> At the time of writing, 2024 data were not yet available. The Nova Scotia-specific factor was obtained from Nova Scotia Power's 2023 total system emissions data (4,931,152 CO<sub>2</sub> eq tonnes) and total electricity generation (10,442 GWh) was drawn from the following two sources: Nova Scotia Power, Total System Emissions, <https://www.nspower.ca/clean-energy/air-emissions-reporting> (last accessed September 27,

**Table 33: Evaluated 2024 SEM Gross GHG Emission Reductions**

|                                                                                             | Total |
|---------------------------------------------------------------------------------------------|-------|
| Gross Energy Savings – at the Generator (GWh)                                               | 4,478 |
| Nova Scotia-specific GHG Emissions Factor for Electricity Production (tonnes of CO2 eq/GWh) | 472.2 |
| Gross Annual GHG Emission Reductions (tonnes of CO2 eq)                                     | 2,114 |

## 11.3 Net Savings

The Evaluator determined the net energy and peak demand savings, i.e. the electrical energy and peak demand savings that can be reliably attributed to the program component, by estimating the NTGR. More precisely, the NTGR represents the positive or negative impacts of spillover and free-ridership effects on gross savings.

As recommended in the 2023 evaluation, the Evaluator applied the assumption that the SEM NTGR was equal to 1.

### 11.3.1 Evaluated Net Savings

Since spillover and free-ridership effects were considered nil, net SEM impacts are equal to the gross savings generated by the program component. The 2024 SEM net electrical energy and peak demand savings were estimated at 4.478 GWh and 0.538 MW at the generator respectively. The net electrical energy savings resulted in 2,114 tonnes of CO2 eq in net annual GHG emission reductions.

As outlined in Figure 14 below, SEM surpassed its electrical energy and peak demand savings targets by 6% and 14% respectively.

**Figure 14: 2024 SEM Targets and Evaluated Results**

## 11.4 Realization Rate

A comparison of the electrical energy and peak demand savings established through this evaluation and those tracked by E1 is presented in Table 34 below. It also includes the realization rate, representing the ratio of evaluated net savings to tracked net savings, for both electrical energy savings and peak demand savings.

2024) and Emera Inc., Emera Inc. 2023 Annual Report, p. 31, available at [https://s25.q4cdn.com/978989322/files/doc\\_financials/2023/ar/Emera\\_2023\\_AR\\_FINAL.pdf](https://s25.q4cdn.com/978989322/files/doc_financials/2023/ar/Emera_2023_AR_FINAL.pdf) (last accessed September 27, 2024).

| Peak Demand Savings                                                                                                 |               |      |       |             |      |                  |
| Tracked Savings by E1                                                                                               | 0.537         | MW   | 1.00  | 0.537       | MW   | 100%             |
| Evaluation Results                                                                                                  | 0.538         | MW   | 1.00  | 0.538       | MW   |                  |
| * The average NTGR values presented in this table correspond to the ratios of net savings to gross savings for SEM. |               |      |       |             |      |                  |

The evaluated net electrical energy savings were less than 1% below the tracked value due to two projects whose savings were slightly adjusted downward.

The evaluated peak demand savings were less than 1% above the tracked value due to three projects that saw their peak demand savings decreased and one project that saw its peak demand increased.

## 12 SEM Key Findings and Recommendations

As mentioned previously, the main objectives of the 2024 SEM evaluation were as follows:

- › Calculate SEM gross and net results, namely electrical first-year and lifetime energy savings, peak demand savings, and avoided GHG emissions.

This section presents the Evaluator's key findings related to the above objectives. The Evaluator has no recommendations pursuant to the 2024 SEM evaluation.

### **2024 SEM-Finding: SEM exceeded its net electrical energy and peak demand savings targets.**

In 2024, SEM achieved 4.478 GWh and 0.538 MW in net electrical energy and peak demand savings respectively. Electrical energy savings were 6% above the planned energy savings of 4.222 GWh and 14% above the planned peak demand savings of 0.470 MW.

### **2024 SEM-Finding: The SEM participation level has remained stable over the past five years. Electrical energy savings per participant were similar to those in 2023.**

There were 12 participants in SEM in 2024, nine continuing participants and three new participants. Moreover, seven of the 12 participants completed projects with savings in 2024, which corresponds to the average for the previous five years.

### **2024 SEM-Finding: The M&V methodologies applied to quantify savings were generally appropriate and accurate. The quality of peak demand savings estimates was greatly improved compared to previous years.**

While there continued to be adjustments to electrical energy savings and peak demand savings, these adjustments were less than 1%. While not perfect, the Service Provider appears to be more consistently applying the guideline written by E1 for calculating peak demand savings.

## CONCLUSION

Table 35 presents the participation levels, net-to-gross ratios (NTGRs), evaluated gross and net savings at the generator, annual GHG emission reductions, as well effective useful life (EUL) values for each Custom Incentives program component and for the program as a whole.

**Table 35: Overall 2024 Custom Incentives Participation and Evaluated Savings**

|                                                                                                                  | Participation Level |                    | Gross Savings |                  | NTGR* | Net Savings |                  |

| * The NTGRs listed in this table match the rounded averages obtained from dividing net savings by gross savings. |                     |                    |               |                  |       |             |                  |

Figure 15 and Figure 16 below respectively illustrate the net electrical energy and peak demand savings targets for each program component and Custom Incentives as a whole as well as whether targets were achieved in 2024. Custom Incentives was aimed at achieving 31.258 GWh in net electrical energy savings and 4.571 MW in net peak demand savings at the generator for 2024. The program surpassed both the net electrical energy and demand savings targets. Custom was the largest contributor to total program net electrical energy and peak demand savings.

## Introduction

I am with \_\_\_\_\_ and we are conducting an evaluation of the Custom Retrofit program offered by Efficiency Nova Scotia.

This interview could take up to 30 minutes. Is this still a good time for you?

We would like to better understand your organization's decision-making process regarding the energy efficiency project you completed as part of the Custom Retrofit program. We are looking to understand how you made the decision to implement your energy efficiency Retrofit\* project for the building located at **[SPECIFY LOCATION\*]**. We will refer to this as your decision "to implement your energy efficiency project" throughout this interview.

**\*[IF MORE THAN ONE COMPLETED PROJECT IS BEING REVIEWED]** This interview specifically refers to the following projects that you have implemented **[SPECIFY PROJECT NAMES AND LOCATIONS]**, so please think of both of/all these projects when answering the questions. Let me know during the interview when and how your responses differ by project.

Your responses will be kept confidential, and results from all interviews will be provided in aggregate format. Your responses will not affect the incentive amount you have or will receive for this project.

### A. Identifying Key Decision-makers

A1. We would like to speak with someone that played a key role in the financial decision to implement the energy efficiency project for your organization. Are you that person?

- 1. Yes
- 2. No
- 98. Don't know
- 99. Refused

A2. **[IF A1=YES OR DK/REFUSE]** Please describe your role in the decision-making process for this project.

96. Specify:

A3. **[IF A1=NO]** Could you provide the name, role, and contact information for someone who played a key role in the decision to implement the energy efficiency project? **[RECORD INFORMATION; THANK & TERMINATE AND REACH OUT TO NEW CONTACT]**

Specify Name:

Specify role:

Specify contact info (email and/or phone):

## B. Awareness and Participation

- B1. Without commenting on your participation in the Custom Retrofit program for now, why did your organization decide to implement the energy efficiency upgrades we are discussing today?  
**[DO NOT READ]**

Specify:

Pre-coded answers **[DO NOT READ]**:

1. Lower operation costs
2. Energy policy in my organization
3. Environmental reasons/energy efficiency
4. Competitors are doing it
98. Don't know
99. Refused

- B2. How did you first hear about the Custom Retrofit program?

Specify

- B3. Why did your organization decide to participate in the Custom Retrofit program?

Specify:

## C. Free-ridership

- C1. Had your organization finalized the design and planning of the energy efficiency project BEFORE knowing that you would receive an incentive from Efficiency Nova Scotia?

1. Yes
2. No
98. Don't know
99. Refused

- C2. **[IF C1=YES]** When you decided to move forward with the energy efficiency project, how confident were you that you would receive an incentive from Efficiency Nova Scotia? Were you **[READ]**?

1. Very confident
2. Somewhat confident
3. Not very confident
4. Not at all confident
98. (Don't know)
99. (Refused)

Efficiency Nova Scotia gave your organization a rebate of \$<STUDY INCENTIVE> for the [INVESTIGATION OR FEASIBILITY] study and \$<IMPLEMENTATION INCENTIVE> for the project implementation, totalling <TOTAL> in incentives for your project.

C3. I would like to understand the impact of this incentive on the financial case for your project. To what extent did these financial incentives improve the payback period for this project?

1. The financial incentives improved the payback period by a **very** significant margin; or
2. The financial incentives improved the payback period by a **somewhat** significant margin; or
3. The financial incentives **DID NOT** improve the payback period by a significant margin

98. (Don't know)

99. (Refused)

C4. Without the implementation incentive, what is the likelihood that you would have paid the full amount for your energy efficiency project? [READ]

1. Definitely would have.
2. Probably would have.
3. Probably would not have.
4. Definitely would not have.

98. (Don't know)

99. (Refused)

**[ASK IF \$<STUDY INCENTIVE> ≥ 0]**

C5. As part of its Custom Retrofit program, Efficiency Nova Scotia gave your organization a \$<STUDY INCENTIVE> incentive for the [Investigation or Feasibility] study. Without this incentive, what is the likelihood that you would have conducted this study? [READ]

1. Definitely would have.
2. Probably would have.
3. Probably would not have.
4. Definitely would not have.

98. (Don't know)

99. (Refused)

C6. **[ASK IF C5 ≠ 98 OR 99]** Did you use the study as a decision-making tool during the planning stage, to compare and select the potential measures for the energy efficiency project?

1. Yes
2. No
98. Don't know
99. Refused

- C7. You received a \$<IMPLEMENTATION INCENTIVE> implementation incentive based on the energy savings achieved by your energy efficiency project once completed. Without the implementation incentive from Efficiency Nova Scotia, which of the following scenarios would have been the most likely? **[READ]**
1. You would have implemented the exact same energy efficiency project.
  2. You would have implemented a project with fewer or less impactful energy efficiency measures.
  3. You would have implemented the exact same energy efficiency **but** delayed the project by at least a year.
  4. You would not have implemented the project at all.
  98. (Don't know)
  99. (Refused)
- C8. Did your organization use the services of an Onsite Energy Manager (OEM) before implementing the project?
1. Yes
  2. No
  98. Don't know
  99. Refused
- C9. **[IF C8 = YES]** How does having an On-site Energy Manager (OEM) add value to your organization?
- C10. I would like you to rate the importance of the following factors on your decision to implement energy efficiency measures through the Custom Retrofit program, as either very important, somewhat important, not very important, not at all important.

| Factor <b>[READ AND RANDOMIZE]</b>                                                                                                                                                                                                | Responses                   |                                  |             |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|----------------------------------|-------------|
| a. The program financial incentive for the <b>[Investigation or Feasibility Study]</b> .                                                                                                                                          | ___ Response                | ___ 98 Don't Know                | ___ Refused |
| b. The program financial incentive for the implementation of the energy efficiency measures.                                                                                                                                      | ___ Response                | ___ 98 Don't Know                | ___ Refused |
| c. The information from the <b>[Investigation or Feasibility Study]</b> on the energy savings associated with each potential measure.                                                                                             | ___ Response                | ___ 98 Don't Know                | ___ Refused |
| d. The recommendations and technical assistance provided by the Business Development Manager, or other Efficiency Nova Scotia staff on the energy efficiency measures.                                                            | ___ Response                | ___ 98 Don't Know                | ___ Refused |
| e. The non-technical information offered by the Business Development Manager or other Efficiency Nova Scotia staff on energy efficiency such as but not limited to market trends, operating costs, and tradespeople availability. | ___ Response<br>___ Refused | ___ 98 Don't Know/Not applicable |             |
| f. <b>[IF C8 = YES]</b> The Onsite Energy Manager (OEM)'s technical support in identifying the measures to implement as part of the project.                                                                                      | ___ Response                | ___ 98 Don't Know                | ___ Refused |
| g. <b>[IF C8 = YES]</b> The OEM's contribution to the business case for your project or support for project management.                                                                                                           | ___ Response                | ___ 98 Don't Know                | ___ Refused |

## D. Cross-Influence

### [READ AND ROTATE (D1 + D2 TO D3) AND (D4 + D5 TO D7) SEQUENCES]

D1. Before participating in the Custom Retrofit program for this project, had your organization already participated in this program or in other Efficiency Nova Scotia program?

1. Yes, Custom Retrofit.
2. Yes, in another Efficiency Nova Scotia program
3. Yes, both
4. No **(GO TO D4)**
98. Don't know **(GO TO D4)**
99. Refused **(GO TO D4)**

For the following two statements, please respond with either “agree” or “disagree”.

D2. **[IF D1 =YES (1 OR 2 OR 3)]** As a result of your past participation in an Efficiency Nova Scotia program and what you learned from it, you asked a technical staff member from your organization (or a supplier/contractor) to examine the energy efficiency options for your project.

1. Agree
2. Disagree
98. Don't Know
99. Refused

D3. **[IF D1 = YES (1 OR 2 OR 3)]** As a result of your past participation in an Efficiency Nova Scotia program and what you learned from it, you considered the cost effectiveness of the energy efficiency for your project by evaluating the different options for your organization.

1. Agree
2. Disagree
98. Don't Know
99. Refused

D4. Before participating in the Custom Retrofit program had you seen energy efficiency promotional materials from Efficiency Nova Scotia through its website or in brochures, newsletters or presentations?

1. Yes
2. No **(GO TO SECTION E)**
98. Don't know/Refuse **(Go to Section E)**

For the following three statements, please respond with either “agree” or “disagree”.

- 
- D5. **[IF D4 = YES]** The Efficiency Nova Scotia energy efficiency promotional materials you saw were a major factor in your decision to implement the energy efficiency project.
1. Agree
  2. Disagree
  98. Don't Know
  99. Refused
- D6. **[IF D4 = YES]** The Efficiency Nova Scotia energy efficiency promotional materials you saw prompted you to ask a technical staff member from your organization (or a supplier/contractor) to examine the energy efficiency options for your project.
1. Agree
  2. Disagree
  98. Don't Know
  99. Refused
- D7. **[IF D4 = YES]** The Efficiency Nova Scotia energy efficiency promotional materials you saw prompted you to consider the cost effectiveness of the energy efficiency measures by evaluating the different options for your organization.
1. Agree
  2. Disagree
  98. Don't Know
  99. Refused

## **E. Spillover**

- E1. Since taking part in the Custom Retrofit program, have you implemented any additional energy efficiency measures outside of the program?
1. Yes
  2. No **[THANK AND TERMINATE]**
  98. Don't know **[THANK AND TERMINATE]**
  99. Refused **[THANK AND TERMINATE]**
- E2. **[IF E1 = 1]** Did you receive or do you plan on requesting financing or rebates from Efficiency Nova Scotia for the energy efficiency upgrades that you implemented outside of the program?
1. Yes **[THANK AND TERMINATE]**
  2. No
  98. Don't know
  99. Refused

- 
- E3. **[IF E2=NO OR DK/REFUSED]** Please describe these measures by providing the following information
- b. Name of measure
  - c. Type of energy source saved If all non-electric **(THANK AND TERMINATE)**
  - d. Location of the facility If not in Nova Scotia **(THANK AND TERMINATE)**
  - e. Quantity of measures (or physical area covered by the measure in sq meters or sq feet)
  - f. Technical information, such as HOU, capacity, efficiency, etc.
  - g. Estimated savings (in kWh or \$)
  - h. If no quantitative information is available, but the measure is the same as the one implemented through Custom Retrofit , probe participant on its relative size with respect to the Custom Retrofit project evaluated (% of size, area covered by measure, price, etc).
- E4. **[IF E2 = NO OR DK/REFUSED]** How influential was your experience with the energy efficiency project implemented through the Custom Retrofit program on your decision to implement these additional energy efficiency measures outside of the program? **[READ]**
- 1. Very influential.
  - 2. Somewhat influential.
  - 3. Not very influential.
  - 4. Not influential at all.
  - 98. (Don't know)
  - 99. (Refused)
- E5. **[IF E2=NO OR DK/REFUSED]** Why did you implement this project without the assistance of an Efficiency Nova Scotia program?
- 96. Specify
  - 98. Don't know/ Refused

**END**

Those are all the questions I have for you. I thank you very much for your time and cooperation and have a nice day.

## APPENDIX II

### Retrofit Algorithm for Free-Ridership Calculation

| Question                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Answer                                                                                                                                   | Score                                                                           |

| C8                                                                                                                                                                                                                                                   | I would like you to rate the importance of the following five factors on your decision to implement energy efficiency measures through the Custom Retrofit program.<br><br>a. The program financial incentive for the [Investigation or Feasibility Study].<br>b. The program financial incentive for the implementation of the energy efficiency measures.<br>c. The information from the [Investigation or Feasibility Study] on the energy savings associated with each potential measure.<br>d. The recommendations and technical assistance provided by the Business Development Manager, or other Efficiency Nova Scotia staff on the energy efficiency measures.<br>e. The non-technical information offered by the Business Development Manager, or other Efficiency Nova Scotia staff on energy efficiency, such as, but not limited to, market trends, operating costs, and tradespeople availability.<br>f. [IF C10 = YES] The Onsite Energy Manager (OEM)'s technical support in identifying the measures to implement as part of the project.<br>g. [IF C10 = YES] The OEM's contribution to the business case for the project or support for project management. | For each sub-question:<br>1) Very important (0%)<br>2) Somewhat important (25%)<br>3) Not very important (75%)<br>4) Not at all important (100%) | For each sub-question:<br>(Answer) (%)                                |

## APPENDIX IV

### Retrofit and Building Optimization Tracking Sheet Audit

This appendix presents the main results of the tracking sheet audit performed by the Evaluator, which was aimed at:

- › Verifying that all data fields required for the evaluation were included and filled out in the tracking sheet submitted by EfficiencyOne (E1)
- › Ensuring that tracked results were accurate by:
  - › Verifying that parameters used to calculate program results (gross and net energy and peak demand savings at the generator) were consistent with previous evaluation results
  - › Validating that all calculation steps were performed consistently

Table 1, 2 and 3 present the corrected tracked savings resulting from all changes made by the Evaluator for Retrofit, Building Optimization and the two programs combined.

**Table 1: 2024 Retrofit Corrected Tracked Savings**

| Program Component Result                | Tracked by E1 |      | Corrected Tracked Value |      | Relative Difference |
|-----------------------------------------|---------------|------|-------------------------|------|---------------------|
|                                         | Value         | Unit | Value                   | Unit |                     |
| Gross Energy Savings – at the Generator | 26.198        | GWh  | 26.115                  | GWh  | -0.32%              |
| Gross Demand Savings – at the Generator | 2.688         | MW   | 2.688                   | MW   | 0.00%               |
| Net Energy Savings – at the Generator   | 20.764        | GWh  | 20.719                  | GWh  | -0.21%              |
| Net Demand Savings – at the Generator   | 2.169         | MW   | 2.169                   | MW   | 0.00%               |

**Table 2: 2024 Building Optimization Corrected Tracked Savings**

| Program Component Result                | Tracked by E1 |      | Corrected Tracked Value |      | Relative Difference |
|-----------------------------------------|---------------|------|-------------------------|------|---------------------|
|                                         | Value         | Unit | Value                   | Unit |                     |
| Gross Energy Savings – at the Generator | 1.954         | GWh  | 1.954                   | GWh  | 0.00%               |
| Gross Demand Savings – at the Generator | 0.102         | MW   | 0.102                   | MW   | 0.00%               |
| Net Energy Savings – at the Generator   | 1.778         | GWh  | 1.778                   | GWh  | 0.00%               |
| Net Demand Savings – at the Generator   | 0.093         | MW   | 0.093                   | MW   | 0.00%               |

**Table 3: 2024 Retrofit and Building Optimization Combined Corrected Tracked Savings**

| Program Component Result                | Tracked by E1 |      | Corrected Tracked Value |      | Relative Difference |
|-----------------------------------------|---------------|------|-------------------------|------|---------------------|
|                                         | Value         | Unit | Value                   | Unit |                     |
| Gross Energy Savings – at the Generator | 28.152        | GWh  | 28.068                  | GWh  | -0.30%              |
| Gross Demand Savings – at the Generator | 2.790         | MW   | 2.790                   | MW   | 0.00%               |
| Net Energy Savings – at the Generator   | 22.541        | GWh  | 22.497                  | GWh  | -0.20%              |
| Net Demand Savings – at the Generator   | 2.262         | MW   | 2.262                   | MW   | 0.00%               |

There were no substantial differences between the tracked and corrected tracked energy and demand savings. The minor changes in energy savings were due to adjustments made to line loss factors.

# APPENDIX V

## Retrofit and Building Optimization Project Review Protocols

### Project Review Protocol

The Evaluator used the same project review protocol in 2024 as the one used for the 2023 Custom Retrofit evaluation. The protocol includes questions and assessment fields for measurement and verification (M&V) plans and reports to ensure that the review is consistent with past evaluation recommendations. The protocol also includes dedicated worksheets containing measure specific data fields for individual project measures.

Prior to conducting telephone project review interviews or on-site visits, the Evaluator reviewed all project documentation submitted by EfficiencyOne (E1). Those documents included, although were not limited to, the following: Scoping and/or feasibility studies; energy efficiency measure savings calculations; project development agreements; M&V reports; and email correspondence.

The Evaluator used the protocol form presented below to collect technical data and summarize information such as project details, key parameters to be reviewed during the telephone project review interviews, and previous M&V activities. Other collected technical information includes, although is not limited to, equipment operating schedules, equipment specifications and quantities, baseline conditions, typical equipment loads, and changes that occurred since M&V was conducted.

Custom Retrofit  
Efficiency Nova Scotia  
On-Site Visit Protocol - 2024

1. General Information

Virtual Visit Date:  Team:

Contact Name:

Project ID:

Contact Title:

Project Type (Regular Retrofit (project type) / Compressed Air/ Bopt) :

Role on the project:

Company Name:

Administer FR/SO?

Facility Name:

Alternate FR/SO contact:

Address:

Contact Phone:

Consultant:

Email:

Other people met during the visit:

Type of building: 

|                          |                          |  |
|--------------------------|--------------------------|--|
| Commercial/institutional | Industrial/manufacturing |  |
| Municipal                | Other (specify)          |  |

Specify:

2. Facility and Project Description

Facility Description: *Outline a quick description of the facility and its primary operation/purpose.*  
*NOTE: PC Users "Alt+Enter" for new line in cell. MAC Users "CMD+Option+Enter".*

Project Description: *Indicate the key variables & observations from all available reports. These notes will serve to guide the virtual visit and identify the main information to collect and/or verify.*

Measure #1:

Measure #2:

### 3. M&V Plans and Documentation

1a. Is there any documentation that describes the plan for M&V dated from before the project takes place? (Y/N)

IF ANSWER TO QUESTION 1a. IS "NO", GO TO NEXT SECTION

1b. Does this document provide a description of:

- Selection and substantiation of the project measurement boundary and justification of IPVMP Option? (Y/N)
- Selection and substantiation of the baseline measurement period? (Y/N)
- Selection and substantiation of the performance measurement period? (Y/N)
- Description of the savings calculation methodology? (Y/N)
- Consideration of actual and potential independent variables? (Y/N)
- Consideration of actual and potential interactive effects? (Y/N)
- Description of the data collection approach for capturing relevant dependant and independent variables? (Y/N)
- Consideration of potential operational impacts and non-routine adjustments? (Y/N)
- Consideration of potential COVID impacts and non-routine adjustments? (Y/N)

2. Is the scope and detail of the documentation above commensurate with the energy and demand savings, budget, incentive level or technical complexity of the project in general alignment with the table from tab "M&V Table"?

- For the M&V plan (Y/N)
- For the M&V results (Y/N)

Please see table to the right for definitions of Small to Large projects

3. If an M&V plan was prepared ahead of project completion, was it followed and reflected in the M&V Report? (Y/N)

#### Intermediate M&V score - Pre-evaluation

#DIV/0!

Notes before interview. Include specific questions to be asked (highlight them if needed to be sure not to forget to ask them)

Écrire questions en rouge (pour interview) et les notes en noir

Notes during/after interview

### 4. On-site or Virtual Review

Filled out on subsequent worksheets, one worksheet for each measure.

## 5. Other questionnaires

|                                        |                      |       |
|----------------------------------------|----------------------|-------|
| Market questionnaire filled-in         | <input type="text"/> | (Y/N) |
| Free-ridership questionnaire filled-in | <input type="text"/> | (Y/N) |
| Spillover questionnaire filled-in      | <input type="text"/> | (Y/N) |

Sections below to be filled after the visit

## 6. Estimated Useful Life "EUL" of the project

|                             |                      |                                                         |
|-----------------------------|----------------------|---------------------------------------------------------|
| Type of replacement         | EUL                  |                                                         |
| Measure #1                  | <input type="text"/> | <input type="text"/>                                    |
| Measure #2                  | <input type="text"/> | <input type="text"/>                                    |
| Tracked Project EUL (yrs)   | <input type="text"/> | Refer to project documentation for tracked baseline EUL |
| Evaluated Project EUL (yrs) | <input type="text"/> | Refer to program document for standard EUL to be used   |
| Explanation                 | <input type="text"/> |                                                         |

## 7. Energy and Demand Savings Adjustment: PAR MESURE

|                         |  |                       |                |           |                      |                |              |  |
|-------------------------|--|-----------------------|----------------|-----------|----------------------|----------------|--------------|--|
| Measure #1              |  | *Name of the Measure* |                |           |                      |                |              |  |
|                         |  |                       | Tracking sheet | Evaluator | % of Tracked savings | Project status | Finish month |  |
| Electricity Savings     |  | kWh/yr                |                |           |                      |                |              |  |
| Peak Demand Savings     |  | kW                    |                |           |                      |                |              |  |
| Peak Coincidence Factor |  | -                     |                |           |                      |                |              |  |

|                         |  |                       |                |           |                      |                |              |
|-------------------------|--|-----------------------|----------------|-----------|----------------------|----------------|--------------|
| Measure #2              |  | *Name of the Measure* |                |           |                      |                |              |
|                         |  |                       | Tracking sheet | Evaluator | % of Tracked savings | Project status | Finish month |

## 8. Summarize Project Adjustments and Final Savings Values - SUMMARY FOR E1

If any adjustments were made to the energy savings, demand savings or PCF, describe the rationale and provide calculations.

See Templates sheet, the idea is to have uniform language across all project reviews, since these summaries will be used to produce the Summary of Adjustment spreadsheet for E1.

#### 4. On-site or Virtual Review (continued)

Section to be filled out with questions prior to virtual visits, and answers to be included during the call. Create new worksheet and repeat for each measure, as needed.

|                   |                              |
|-------------------|------------------------------|
| <b>Measure #1</b> | <i>*Name of the Measure*</i> |
|-------------------|------------------------------|

##### Validation of the measure

Validate the installation and quantities. Do we have pictures (nameplate) in the file? Can we see it during the call? Is there invoices confirming the quantities?

Notes before interview. Include specific questions to be asked (highlight them if needed to be sure not to forget to ask them)

Notes during/after interview

##### Baseline

4. Does the baseline measurement match what the project says is the baseline, and is it aligned with program rules?

9. Has anything changed between the baseline and reporting period? (Y/N)

a. If #9 is Y, has a non-routine adjustment been applied? (Y/N)

What is the baseline? Existing equipment, new construction? Was the equipment at the end of its useful life?

Notes before interview. Include specific questions to be asked (highlight them if needed to be sure not to forget to ask them)

Notes during/after interview

##### Operating Schedule

Include notes on schedule and seasonal variations. The operating schedule corresponds to the *typical* one (non-COVID).

6. Is the M&V period appropriate? (Y/N)

a. Do both the baseline and reporting periods cover all ranges of operation parameters?

b. Is M&V occurring in a reasonable period before and right after the EE project was implemented?

c. Does the period capture seasonal effects?

## Savings calculation approach - Projects with M&V

5. Are the M&V boundaries capturing all the energy consumption that's impacted by the project? (Y/N)
7. Are M&V results measured in a short period extrapolated to annual results appropriately? (Y/N)
- a. Is the extrapolation consistent with what a "typical year" should be?
- b. Are operating conditions that were not covered in M&V taken into consideration when developing the extrapolation
8. If a regression is used (based on HDD, tons/day...) to build a performance equation as part of the M&V, is it valid?
- a. The Evaluator will want to be satisfied that the regression makes sense when looking at the physics of the situation.
- b. The Evaluator will want to be satisfied that statistical indicators were used to validate the fitness of the regression?

Report the virtual visit and indicate the key observations and findings made during the interview..

Seasonal Load Profile?  (Y/N) Summer Load Variations?  (Y/N)

| Predicted Results<br>(MWh) | M&V Results          | Percent of<br>Expected (%) | M&V Start Date       | M&V<br>Finish<br>Date | Days in Period |
|----------------------------|----------------------|----------------------------|----------------------|-----------------------|----------------|
| <input type="text"/>       | <input type="text"/> | <input type="text"/>       | <input type="text"/> | <input type="text"/>  | 0              |

### Intermediate M&V score - MEASURE #1

####

Notes before interview. Include specific questions to be asked (highlight them if needed to be sure not to forget to ask them)

Notes during/after interview

### COVID Impact for Measure #1

Include notes on how calculated savings are impacted by COVID, if so.

Detail any adjustment, along with the rational, needed to bring back the savings to a typical year.

10. Has this measure been impacted by COVID? (Y/N)
- a.i. Hours of occupancy, or production schedules? (Y/N)
- a.ii. Level of occupancy during occupied hours, or production intensity during production periods? (Y/N)
- b. If so, how has this impacted the selection of the baseline or reporting periods M&V methods? (Y/N)
- c. Is a non-routine adjustment warranted? (Y/N)
- d. Has a non-routine adjustment been appropriately applied? (Y/N)

Notes before interview. Include specific questions to be asked (highlight them if needed to be sure not to forget to ask them)

Notes during/after interview

**Peak Demand Savings?** YES ☐ NO ☐

*Notes on peak demand savings (Nova Scotia Peak Period: weekdays between 5 and 7 p.m. between Dec and Feb)*

**Are demand savings based on measurements?** ☐ (Y/N)

*Notes before interview. Include specific questions to be asked (highlight them if needed to be sure not to forget to ask them)*

*Notes during/after interview*

**Interactive Effects?** YES ☐ NO ☐

*Briefly describe interactive effects for the project and relevant information on **heating/cooling system** as required.*

*Notes before interview. Include specific questions to be asked (highlight them if needed to be sure not to forget to ask them)*

*Notes during/after interview*

## APPENDIX VI

### Custom Adjustment Ratio Calculation Example

---

This appendix provides an example of the project review process and calculations used to adjust the energy savings results for a regular Retrofit project. The calculation described below presents the adjustments made to a refrigeration retrofit project that took place at a lobster holding facility. The adjustments were based on information collected during a phone call as well as a review of project documentation carried out by the Evaluator.

The project background is presented first, followed by the savings tracked by E1, revised savings, and the rationale behind the adjustments.

#### Project Background

The participant operates four lobster holding tanks that are fed with seawater, one of which was previously unrefrigerated (Tank #1), while the other three (Tanks #2, #3, and #4) each had a refrigeration unit and a heat exchange system to maintain optimal water temperatures inside the tanks. The Retrofit project consisted of two measures: Replacing the existing R22 refrigerant with a more efficient R449A refrigerant; and adding refrigeration units on Tanks #2 and #4. The participant provided performance data sheets for all refrigeration units, including refrigeration capacity and overall consumption, for both the efficient and baseline cases (for the baseline case, performance data were provided for units using R404 refrigerant that was used as a proxy for the existing R22 refrigerant given their similar properties).

#### Tracked Savings Calculation

For this project, an E1 project engineer created an Excel spreadsheet to calculate electrical energy consumption for all four tanks for both the base cases and efficient cases, using the refrigeration unit performance data from the manufacturer, weather and seawater temperature data, as well as on-site measurements (to validate the efficiency of the heat exchange units). The spreadsheet also calculated peak demand savings that occur during the utility's winter peak demand period (December to February, from 5 pm to 7 pm).

#### Revised Savings Calculation

The Evaluator found that the assumptions and the analysis performed by E1 were generally sound. Moreover, after reviewing the savings calculations, the Evaluator found mistakes in some of the Excel formulas used to calculate the refrigeration load for each of the four tanks. These formulas did not use the correct target temperatures to calculate the temperature difference ( $\Delta T$ ), which in turn is used to calculate the refrigeration load. The Evaluator corrected this mistake, which caused a downward adjustment to the consumption levels and demand savings.

The Evaluator also adjusted the effective useful life (EUL) for this project. Since the refrigerant was changed in a mix of existing and new refrigeration units, the remaining useful life of the measure varies across units (the more efficient refrigerant will stop generating savings when each unit reaches the end of its useful life). Therefore, the Evaluator calculated an average EUL weighted by the first-year savings generated by each unit and applied it to total project savings. Consequently, the EUL was adjusted from 15 years to 11 years.

## Adjustment Ratio Calculation

Adjustment ratios are determined by comparing revised savings values with tracked savings values. Due to the revisions made to this project, the calculated adjustment ratio for energy savings was 0.825.

$$\frac{\text{Revised ES}}{\text{Tracked ES}} = \frac{105,425 \text{ kWh}}{127,826 \text{ kWh}} = 0.825$$

## Introduction – Telephone IDI

I am with Narrative, and we are conducting an evaluation of the Efficiency Nova Scotia Custom New Construction program. This interview should take about 15-20 minutes. Is this still a good time for you?

The purpose of the interview is to better understand your organization's decision to build an energy efficient building, including your choice of energy efficient materials or equipment that exceed building code requirements. During this interview, I will refer to this as your decision "to build a better-than-code building".

**Your responses will be kept confidential, and your comments will be combined with those of other program participants. Your responses will not affect the incentive amount you will received or you have received for this project.**

## Introduction – Online Survey

Narrative Research and Econoler are currently conducting a formal evaluation of the Efficiency Nova Scotia Custom New Construction program. Your organization recently entered into an agreement in **[CPA ACCEPTED DATE]** with Efficiency Nova Scotia to assist in the design of energy efficient measures for the **[INSERT PROJECT NAME]** project. As part of the evaluation process, we are interested in better understanding your organization's decision to build an energy efficient building (also referred to on the survey as a "better-than-code building"), including your choice of energy efficient materials or equipment that exceed building code requirements.

Please take a few minutes to complete the evaluation survey. This should only take you about 15 minutes of your time.

*This survey is administered by Narrative Research and Econoler. Your responses will be kept confidential, and your comments will be combined with those of other program participants. Your responses will not affect the incentive amount you will receive or you have received for this project.*

### A. Identifying Key Decision-makers

A1. **[SINGLE RESPONSE]** Did you play a key role in your organization's decision to build an energy efficient, or better-than-code, building.

1. Yes
2. No
98. I am unsure

A2. **[IF A1=YES; CAPTURE VERBATIM]** Please briefly describe your role in the decision-making process.

A3. **[IF A1= YES; SINGLE RESPONSE]** Did others within your organization play a key role in the decision to build a better-than-code building?

1. Yes
2. No
98. I am unsure

A4. **[IF A1=YES]** Can you provide the name, role, and contact information (email and/or telephone) of one or two of the key decision-makers?

1. No, I cannot provide this information
2. Yes – Please provide the contact information below

**Contact Person 1:**

Name: **[RECORD]**

Role: **[CAPTURE VERBATIM]**

Email and/or phone number: **[RECORD IN FORMAT]**

**Contact Person 2 [OPTIONAL]:**

Name: **[RECORD]**

Role: **[CAPTURE VERBATIM]**

Email and/or phone number: **[RECORD IN FORMAT]**

**[IF A1=YES OR A3=NO OR A4=NO: GO TO SECTION B]**

A5. **[IF A1= NO OR DK; OPTIONAL RESPONSE FOR CONTACT INFO]** Can you provide the names, roles and contact information of one or two people who played a key role in your organization's decision to build a better-than-code building?

1. No
2. Yes – Please provide the contact information below

**Contact Person 1:**

Name: **[RECORD]**

Role: **[CAPTURE VERBATIM]**

Email: **[RECORD IN FORMAT]**

Phone number: **[RECORD NUMERALS ONLY]**

**Contact Person 2 [OPTIONAL]:**

Name: **[RECORD]**

Role: **[CAPTURE VERBATIM]**

Email: **[RECORD IN FORMAT]**

Phone number: **[RECORD NUMERALS ONLY]**

[IF A1= NO or DK: END] These are all the questions I have for you. Thank you very much for your time and cooperation! [SCHEDULE INTERVIEW WITH KEY DECISION-MAKERS]

## B. Project Stage

B1. [MULTIPLE RESPONSE KEEPING CODE 98 AND 99 EXCLUSIVE] Now thinking of the [INSERT PROJECT NAME] project, at what stage is the project currently in? Please select all that apply.

1. Conceptual
2. Design
3. Construction
4. Building Occupancy
96. Other stage – Please specify: \_\_\_\_\_
98. I am unsure
99. I prefer not to say

## C. Free-ridership

C1. [CAPTURE VERBATIM; KEEP CODE 98 & 96 EXCLUSIVE] Why did your organization decide to build a better-than-code building?

CAPTURE VERBATIM

98. I am unsure
99. I prefer not to say

C2. [SINGLE RESPONSE] Was the design of your better-than-code building finalized BEFORE knowing that your organization would receive an incentive from Efficiency Nova Scotia?

1. Yes
2. No
98. I am unsure
99. I prefer not to say

C3. [IF C1=YES; SINGLE RESPONSE] During the design stage, how confident were you that your organization would receive an incentive from Efficiency Nova Scotia?

1. Very confident
2. Somewhat confident
3. Not very confident
4. Not at all confident
98. I am unsure
99. I prefer not to say

- C4. **[SINGLE RESPONSE]** Which one of the following best represents the impact of the financial incentive offered by Efficiency Nova Scotia on the financing of the new building project?
1. The incentive from Efficiency Nova Scotia reduced the cost of the building's energy efficiency measures, allowing the project to be **within its approved budget**.
  2. The incentive from Efficiency Nova Scotia reduced the cost of the building's energy efficiency measures, significantly **strengthening the case for the overall project from a financial perspective**.
  3. The incentive from Efficiency Nova Scotia reduced the cost of the building's energy efficiency measures, **but even without the financial incentive, you would have included the same measures** for other reasons.
  4. The incentive from Efficiency Nova Scotia did not have a significant impact on the financing of the project.
98. I am unsure  
99. I prefer not to say
- C5. **[SINGLE RESPONSE]** You received an incentive of **<INSERT MODELING INCENTIVE AMOUNT>** from Efficiency Nova Scotia for your building's energy model. Without this incentive, what is the likelihood that you would have hired an energy modeling consultant for your project?
- INSERT 0-10 SCALE WITH END POINTS: 0=VERY UNLIKELY AND 10=VERY LIKELY
98. Don't know  
99. I prefer not to say
- C6. **[SINGLE RESPONSE]** Did the energy modeling consultant help you assess different options available for building envelope and HVAC equipment?
1. Yes
  2. No
98. I am unsure  
99. I prefer not to say
- C7. **[SINGLE RESPONSE]** Your organization will receive an incentive from Efficiency Nova Scotia specifically for the implementation of the energy efficiency measures. Without this incentive, which of the following scenarios would have been the most likely?
1. Your organization would have designed the exact same better-than-code building.
  2. Your organization would have designed a less efficient building but still exceeded the minimum energy efficiency requirements prescribed in the building code.
  3. Your organization would have designed a less efficient building that met the minimum energy efficiency requirements prescribed in the building code.
98. I am unsure  
99. I prefer not to say

C8. **[IF C7=2; SINGLE RESPONSE PER STATEMENT; DO NOT RANDOMIZE]** Without the incentive provided by Efficiency Nova Scotia or the expertise provided by the energy modeler, what is the likelihood that your organization would have:

- a. designed a building with HVAC equipment as efficient as those you installed
- b. designed a building with **an envelope as efficient as the one you built, including insulation levels and glazing performance**
- c. designed a building with **as many efficiency measures as you included**

INSERT 0-10 SCALE WITH END POINTS: 0=VERY UNLIKELY AND 10=VERY LIKELY

98. I am unsure

99. I prefer not to say

C9. **[IF C7=2 AND IF AVERAGE (C8a, C8b and C8c)  $\geq$  8; CAPTURE VERBATIM; KEEP CODE 98 AND 99 EXCLUSIVE]** You mentioned that, without an incentive from Efficiency Nova Scotia or the energy modeler, you would have designed a less efficient building than your current design. Please explain how your building would have been different than what it is right now.

CAPTURE VERBATIM

98. I am unsure

99. I prefer not to say

C10. **[SINGLE RESPONSE PER STATEMENT; DO NOT RANDOMIZE]** Rate the influence of the following factors in your decision to build a better-than-code building.

- a. The program financial incentive for energy modeling.
- b. The program financial incentive for implementation of energy efficiency measures.
- c. The insights gained from the energy modeling regarding the energy savings associated with each potential measure.
- d. The recommendations and technical assistance provided by the energy modeler, Business Development Manager, onsite energy manager, or other Efficiency Nova Scotia staff.
- e. The non-technical information offered by the energy modeler, Business Development Manager, onsite energy manager, or other Efficiency Nova Scotia staff on building better-than-code buildings, for example, the market trends, building certifications, operating costs, and tradespeople availability, among other things.

INSERT 0-10 SCALE WITH END POINTS: 0=NOT AT ALL IMPORTANT AND 10=EXTREMELY IMPORTANT

98. I am unsure

99. I prefer not to say

## D. Cross-Influence

D1. **[SINGLE RESPONSE]** Before participating in the Custom New Construction program for the **[INSERT PROJECT NAME]** project, had your organization already participated in Custom New Construction or in another Efficiency Nova Scotia program?

1. Yes, Custom New Construction
2. Yes, in another Efficiency Nova Scotia program
3. Yes, both
4. No
98. I am unsure
99. I prefer not to say

**[IF D1=4, 98 OR 99: SKIP TO D4]**

**[ASK D2 AND D3 IF D1= YES (CODE 1-3); SHOW INTRO ON SAME PAGE AS D2 AND D3]** To what extent do you agree or disagree with the following two statements:

D2. **[ASK IF D1= YES (CODE 1-3); SINGLE RESPONSE]** Because of your organization's previous participation in an Efficiency Nova Scotia program and what you learned from it, you/your organization asked a technical staff member or energy modeler to examine the energy efficiency options for your current building project.

INSERT 0-10 SCALE WITH END POINTS: 0=COMPLETELY DISAGREE AND 10=COMPLETELY AGREE

98. I am unsure
99. I prefer not to say

D3. **[ASK IF D1= YES (CODE 1-3); SINGLE RESPONSE]** Because of your organization's previous participation in an Efficiency Nova Scotia program and what you learned from it, you/your organization looked at the cost effectiveness of the energy efficiency measures in your new building by evaluating the different options available.

INSERT 0-10 SCALE WITH END POINTS: 1=COMPLETELY DISAGREE AND 10=COMPLETELY AGREE

98. Don't know
99. I prefer not to say

D4. **[SINGLE RESPONSE]** Before participating in the New Construction program, had you seen energy efficiency promotional materials distributed by Efficiency Nova Scotia through its website, advertisements, brochures, newsletters or presentations?

- 1. Yes
- 2. No
- 98. I am unsure
- 99. I prefer not to say

**[IF D4=2, 98 OR 99: GO TO END]**

**[ASK D5 TO D7 IF D4=YES; SHOW INTRO AND D5-D7 ON SAME PAGE]** To what extent do you agree or disagree with the following three statements:

D5. **[ASK IF D4=YES; SINGLE RESPONSE]** The energy efficiency promotional materials distributed by Efficiency Nova Scotia through its website, brochures, newsletters, or presentations were a major factor in your organization's decision to build a better-than-code building.

INSERT 0-10 SCALE WITH END POINTS: 0=COMPLETELY DISAGREE AND 10=COMPLETELY AGREE

- 98. I am unsure
- 99. I prefer not to say

D6. **[ASK IF D4=YES; SINGLE RESPONSE]** The energy efficiency promotional materials distributed by Efficiency Nova Scotia through its website, brochures, newsletters or presentations prompted you/your organization to ask a technical staff member or energy modeler to examine the energy efficiency options for your building project.

INSERT 0-10 SCALE WITH END POINTS: 0=COMPLETELY DISAGREE AND 10=COMPLETELY AGREE

- 98. I am unsure
- 99. I prefer not to say

D7. **[ASK IF D4=YES; SINGLE RESPONSE]** The energy efficiency promotional materials distributed by Efficiency Nova Scotia through its website, brochures, newsletters, or presentations prompted you/your organization to consider the cost effectiveness of the energy efficiency measures in your new building by evaluating the different options offered to your organization.

INSERT 0-10 SCALE WITH END POINTS: 0=COMPLETELY DISAGREE AND 10=COMPLETELY AGREE

- 98. I am unsure
- 99. I prefer not to say

**END: [PHONE: These are all the questions I have for you.] [ONLINE SURVEY: That's all the questions we have for you.] Thank you very much for your time and cooperation!**

## Introduction

I am with \_\_\_\_\_ and we are performing an evaluation of the Custom New Construction program service offered by Efficiency Nova Scotia.

This interview should take about 15-20 minutes. Is this still a good time for you?

Through this interview, we hope to better understand your organization's decision-making process regarding the decision to build an energy efficient building. More specifically, we hope to better understand how you made the decision to use energy efficient materials or equipment that exceed building code requirements on efficiency levels. We will refer to this as your decision "to design a better-than-code building" throughout this interview.

Your responses will be kept confidential, and the results will be combined with those of other program participants. Your responses will not affect the incentive amount you will receive for this project.

### A. Identifying Key Decision-makers

A1. We hope to interview the person who played a key role in the decision to build a better-than-code building. Were you a key decision-maker?

- 1. Yes
- 2. No
- 98. Don't know
- 99. Refused

A2. **[IF A1=YES OR DK/REFUSE]** Please describe your role in the decision-making process for this project.

96. Specify:

A3. **[IF A1= YES]** Did others play a key role in the decision to build a better-than-code building? If so, can you provide the name, role, and contact information (either email or telephone) of one or two of the key decision-makers? **[IF NEEDED: WE WILL ONLY CONTACT THEM IF WE REQUIRE FURTHER INFORMATION ABOUT YOUR COMPANY'S DECISION TO BUILD A BETTER-THAN-CODE BUILDING]**

96. Specify:

**[IF A1= YES: GO TO SECTION B]**

A4. **[IF A1=NO]** Who were the people who played a key role in the decision to build a better-than-code building? Can you provide their names, roles, contact information of these decision-makers?

96. Specify:

**[IF A1= NO, DK or REFUSED: END]** These are all the questions I have for you. Thank you very much for your time and cooperation! **SCHEDULE INTERVIEW WITH KEY DECISION-MAKERS**

## B. Free-ridership

B1. Why did your organization decide to build a better-than-code building? **[DO NOT READ. MULTIPLE RESPONSE]**

1. Lower operation costs
2. Energy policy in my organization
3. Environmental reasons/energy efficiency
4. Competitors are doing it
5. Other, specify: \_\_\_\_\_
98. Don't know
99. Refused

B2. Had your organization finalized the design of the new building BEFORE knowing that you would receive an incentive from Efficiency Nova Scotia?

1. Yes
2. No
98. Don't know
99. Refused

B3. **[IF B2=YES]** When you decided to build a better-than-code building, how confident were you that you would receive an incentive from Efficiency Nova Scotia? **[READ]**

1. Very confident
2. Somewhat confident
3. Not very confident
4. Not at all confident
98. Don't know
99. Refused

- B4. I would like to understand the impact of the financial incentives offered by Efficiency Nova Scotia on the financial case for your new building. Which of the following best represents the role of the financial incentive? Did the financial incentives **[READ]**?
1. Reduce the cost of the additional energy efficiency measures included in the building to bring the project **within the pre-determined financial thresholds for approval. OR**
  2. Reduce the cost of the energy efficiency measures, significantly **strengthening the case for the overall project from a financial perspective. OR**
  3. Reduce the cost of the additional energy efficiency measures included in the building, **but even without financial support, you would have included the same measures** for other reasons. OR
  4. Did not have a significant impact on the decision.
  98. (Don't know)
  99. (Refused)
- B5. You received an incentive of **<MODELING INCENTIVE \$\$\$>** from Efficiency Nova Scotia for your energy model. Without this incentive, what is the likelihood that you would have hired an energy modeling consultant for your project?
1. Definitely would have
  2. Probably would have
  3. Probably would not have
  4. Definitely would not have
  98. Don't Know
  99. Refused
- B6. **[IF B5 ≠ 98 OR 99]** Did the energy modeling consultant help you assess different options available for building envelope and HVAC equipment?
1. Yes
  2. No
  98. Don't know
  99. Refused

- B7. You have received an incentive of **<IMPLEMENTATION INCENTIVE \$\$\$>** from Efficiency Nova Scotia specifically for the implementation of the energy efficiency measures. Without this incentive, which of the following scenarios would have been the most likely?
1. You would have designed the exact same building.
  2. You would have designed a less efficient building but still exceeded the minimum energy efficiency requirements prescribed in the building code.
  3. You would have designed a less efficient building that met the minimum energy efficiency requirements prescribed in the building code.
  98. (Don't know)
  99. (Refused)
- B8. **[IF C7 = 2]** Without the incentive provided by Efficiency Nova Scotia or the expertise provided by the energy modeler, what is the likelihood that you would have designed a building with **HVAC equipment as efficient as those you installed?**
1. Definitely would have [DO NOT READ; FOR CALCULATION ONLY: SCORE = 100%]
  2. Probably would have [DO NOT READ; FOR CALCULATION ONLY: SCORE = 75%]
  3. Probably would not have [DO NOT READ; FOR CALCULATION ONLY: SCORE = 25%]
  4. Definitely would not have [DO NOT READ; FOR CALCULATION ONLY: SCORE = 0%]
  98. Don't know
  99. Refused
- B9. **[IF C7 = 2]** Without the incentive from Efficiency Nova Scotia or the expertise provided by the energy modeler, what is the likelihood that you would have designed a building with **a building envelope as efficient as the one you designed, including insulation levels and glazing performance?**
1. Definitely would have [DO NOT READ; FOR CALCULATION ONLY: SCORE = 100%]
  2. Probably would have [DO NOT READ; FOR CALCULATION ONLY: SCORE = 75%]
  3. Probably would not have [DO NOT READ; FOR CALCULATION ONLY: SCORE = 25%]
  4. Definitely would not have [DO NOT READ; FOR CALCULATION ONLY: SCORE = 0%]
  98. Don't know
  99. Refused

- B10. **[IF B7 = 2]** Without the incentive from Efficiency Nova Scotia or the expertise provided by the energy modeler, what is the likelihood that you would have designed a building with **as many efficiency measures as you included?**
1. Definitely would have **[DO NOT READ; FOR CALCULATION ONLY: SCORE = 100%]**
  2. Probably would have **[DO NOT READ; FOR CALCULATION ONLY: SCORE = 75%]**
  3. Probably would not have **[DO NOT READ; FOR CALCULATION ONLY: SCORE = 25%]**
  4. Definitely would not have **[DO NOT READ; FOR CALCULATION ONLY: SCORE = 0%]**
  98. Don't know
  99. Refused
- B11. **[IF B7 = 2 AND IF AVERAGE (B8,B9,B10) ≥ 75%]** You mentioned that, without an incentive from Efficiency Nova Scotia or the energy modeler, you would have designed a less efficient building than your current design. Can you explain how your building would have been different than what it is right now?
- B12. How important were the following factors in your decision to implement the energy efficiency measures in your new building?
- a. The New Construction program financial incentive for energy modeling.
  - b. The New Construction program financial incentive for implementation of energy efficiency measures.
  - c. The insights gained from the energy modeling regarding the energy savings associated with each potential measure.
  - d. The recommendations and technical assistance provided by the energy modeler, Business Development Manager, onsite energy manager, or other Efficiency Nova Scotia staff.
  - e. The non-technical information offered by the energy modeler, Business Development Manager, onsite energy manager, or other Efficiency Nova Scotia staff on building better-than-code buildings, for example, the market trends, building certifications, operating costs, and tradespeople availability, among other things.

For each sub-question:

1. Very important
2. Somewhat important
3. Not very important
4. Not at all important
98. Don't know
99. Refused

## C. Cross-Influence

- C1. Before participating in the Custom New Construction program for the building we discussed today, had you already taken part in Custom New Construction or another Efficiency Nova Scotia program?
1. Yes, Custom New Construction
  2. Yes, in another Efficiency Nova Scotia program
  3. Yes, both
  4. No **[SKIP TO C4]**
  98. Don't know **[SKIP TO C4]**
  99. Refused **[SKIP TO C4]**

**[ASK C2 AND C3 IF C1= YES (codes 1-3)]** Do you agree or disagree with the following statements?

- C2. **[ASK IF C1= YES (codes 1-3)]** Because of your previous participation in an Efficiency Nova Scotia program and what you learned from it, you asked a technical staff member or energy modeler to examine the energy efficiency options for your current building project.
1. Agree
  2. Disagree
  98. Don't know
  99. Refused
- C3. **[ASK IF C1= YES (codes 1-3)]** Because of your previous participation in an Efficiency Nova Scotia program and what you learned from it, you looked at the cost effectiveness of the energy efficiency measures in your new building by evaluating the different options available.
1. Agree
  2. Disagree
  98. Don't know
  99. Refused
- C4. Before participating in the New Construction program, had you seen energy efficiency promotional materials distributed by Efficiency Nova Scotia through its website, advertisements, brochures, newsletters or presentations?
1. Yes
  2. No **[SKIP TO D1]**
  98. Don't know **[SKIP TO D1]**
  99. Refused **[SKIP TO D1]**

**[ASK C5 TO C7 IF C4=YES]** Do you agree or disagree with each of the following statements?

- C5. **[ASK IF C4= YES]** The energy efficiency promotional materials distributed by Efficiency Nova Scotia through its website, brochures, newsletters, or presentations were a major factor in your decision to build a better-than-code building.
- 1. Agree
  - 2. Disagree
  - 98. Don't know
  - 99. Refused
- C6. **[ASK IF C4= YES]** The energy efficiency promotional materials through its website, brochures, newsletters, or presentations distributed by Efficiency Nova Scotia prompted you to ask a technical staff member or energy modeler to examine the energy efficiency options for your building project.
- 1. Agree
  - 2. Disagree
  - 98. Don't know
  - 99. Refused
- C7. **[ASK IF C4= YES]** The energy efficiency promotional materials through its website, brochures, newsletters, or presentations distributed by Efficiency Nova Scotia prompted you to consider the cost effectiveness of the energy efficiency measures in your new building by evaluating the different options offered to your organization.
- 1. Agree
  - 2. Disagree
  - 98. Don't know
  - 99. Refused

## D. Barriers and Motivations

D1. What were your primary concerns when you were considering building a high-efficiency building?  
**[DO NOT READ. MULTIPLE RESPONSE]**

1. (Cost of energy efficient technologies)
1. (Cost of energy modeling)
2. (Lower profits)
3. (Speed of construction)
4. (Lack of company expertise to design high-efficiency buildings)
5. (Performance of energy efficient technologies)
6. (Developer or investor satisfaction or retention)
7. (Building occupant satisfaction or comfort)
96. (Other [SPECIFY \_\_\_\_\_])
98. (Don't know)
99. (Refused)
97. (None/no concerns)

D2. Were there additional higher-efficiency technologies that you would have liked to have installed but you did not include in the project?

1. Yes
2. No
98. (Don't know)
99. (Refused)

D3. [ASK IF D2=1] What were these technologies? [RECORD VERBATIM RESPONSE]

D4. **[ASK IF D2=1]** Why did you decide not to include these technologies? **[RECORD VERBATIM RESPONSE]**

1. (Higher cost)
2. (Lower profits)
3. (Slower speed of construction)
4. (Unavailability of the technologies in the marketplace)
5. (Lack of contractor or market labor to install and/or maintain the technologies)
6. (Lack of company expertise with the technologies)
7. (Complexity of technology installation)
8. (Complexity of technology operations and maintenance)
9. (Performance of the technologies)
10. (Developer or investor satisfaction or retention)
11. (Building occupant satisfaction or comfort)
96. (Other [SPECIFY \_\_\_\_\_])
98. (Don't know)
99. (Refused)

## E. Program satisfaction

E1. On a scale from 1 to 10 (where 1 = not at all satisfied and 10 = very satisfied) ...

- a. how would you rate your satisfaction with each of the following aspects of the New Construction program?
- b. If less than 8, please explain the reason(s) for your score.

| Aspects of the program [READ AND RANDOMIZE]                                                                 | Score                                 | Reason |
|-------------------------------------------------------------------------------------------------------------|---------------------------------------|--------|
| 1. The overall program                                                                                      | __ Response __98 DK __99 Ref __97 N/A |        |
| 2. The responsiveness of Efficiency Nova Scotia employees to your requests and enquiries in a timely manner | __ Response __98 DK __99 Ref __97 N/A |        |
| 3. The speed with which the application was approved                                                        | __ Response __98 DK __99 Ref __97 N/A |        |
| 4. The value of the program or service relative to the time and cost involved                               | __ Response __98 DK __99 Ref __97 N/A |        |
| 5. The ability to provide estimates of the savings or return on investment associated with the program      | __ Response __98 DK __99 Ref __97 N/A |        |
| 6. The technical expertise of Efficiency Nova Scotia employees related to the program                       | __ Response __98 DK __99 Ref __97 N/A |        |

E2. Has your company experienced any challenges with the program over the last year?

- 1. Yes
- 2. No
- 98. Don't know
- 99. Refused

E3. **[ASK IF E2=1]** Please describe the challenges you encountered **[OPEN RESPONSE]**

E4. Do you have any suggestions to improve the program? **[OPEN RESPONSE]**

Record: \_\_\_\_\_

☐ No suggestion at this time

I have a few more questions to ask you about GHG emissions and electrification. Would you have another 3-4 minutes?

## **F. GHG Emissions and Electrification (Builders)**

F1. Would you say that reducing GHG emissions is...**[READ]**

- 1. ...very important to your company?
- 2. ...important to your company?
- 3. ...of little importance to your company?, or
- 4. ...not at all important to your company?
- 98. Don't know
- 99. Refused

F2. **[ASK IF F1=1-2]** Has your desire to reduce GHG emissions in your buildings influenced your participation in the New Construction program?

- 1. Yes
- 2. No
- 98. Don't know
- 99. Refused

F3. **[ASK IF F2=1]** How has it influenced your participation? **[RECORD VERBATIM RESPONSE]**

F4. Would you say that electrification is...**[READ]**

1. ...very important to your company?
2. ...important to your company?
3. ...of little importance to your company?, or
4. ...not at all important to your company?
98. Don't know
99. Refused

F5. **[ASK IF F4=1-2]** Has your opinion regarding electrification influenced your participation in the New Construction program?

1. Yes
2. No
98. Don't know
99. Refused

F6. **[ASK IF F5=1]** How has it influenced your participation? **[RECORD VERBATIM RESPONSE]**

## **G. Building codes**

G1. In April 2025, Nova Scotia will adopt the National Energy Code of Canada for Buildings 2020 (NECB2020). Would you say that the adoption of NECB2020 increases, decreases, or has no impact on your likelihood to participate in the New Construction program in the future?

1. Increases
2. Decreases
3. Has no impact
98. Don't know
99. Refused

G2. **[IF G3=1-3]** Why do you say that? **[RECORD VERBATIM RESPONSE]**

## **END**

Those are all the questions I have for you today. Thank you for your time and the valuable feedback you have provided.

## APPENDIX IX

### New Construction Non-Participant Modeler Guide

#### GUIDE FOR INTERVIEWS WITH Non-Participant and new ENERGY Modelers

**Table 5: Overview of Data Collection Activity**

| Descriptor                       | This Instrument                           |
|----------------------------------|-------------------------------------------|
| Instrument Type                  | Semi-directed in-depth interview          |
| Estimated Time to Complete       | 15 Minutes                                |
| Target Audience                  | › New or Non-Participant Modelers         |
| › Expected Number of Completions | › Non-Participant or New Modelers (n = 3) |
| Contact List Source              | Efficiency One                            |
| Fielding Firm                    | Econoler                                  |
| Estimated Timeline for Fielding  | November 2024                             |

**Table 6: Research Objectives and Questions**

| Research objective                                                                            | Research Questions                                                                           | Section/Question # |
|-----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|--------------------|
| › Explore opportunities to expand program presence outside of electrically heated MURB market | › Are projects outside of Halifax area underrepresented in New Construction?                 | A3<br>E9           |
|                                                                                               | › What is the awareness level of the program among non-MURB builders and energy modellers?   | A2<br>Section E    |
|                                                                                               | › What are the motivations and barriers for non-MURB builders to participate in the program? | A2<br>Section B    |
|                                                                                               | › What actions could be taken by the program to target more non-MURB participants?           | E9                 |
| › Update program service logic                                                                | › What are the barriers to program participation?                                            | Section B          |

## Introduction

Hello, may I speak with [Contact name]?

My name is [Interviewer name] and I'm calling from Narrative Research, a Halifax based market research firm on behalf of Efficiency Nova Scotia. We are conducting an evaluation of energy efficiency services provided by Efficiency Nova Scotia.

We would appreciate your help in answering questions about the commercial new construction market in Nova Scotia. The information you provide will be used to help Efficiency Nova Scotia improve their new construction program offerings.

**[IF NEEDED: EFFICIENCY NOVA SCOTIA'S NEW CONSTRUCTION PROGRAM PROVIDES SUPPORT FOR THE DESIGN AND CONSTRUCTION OF ENERGY EFFICIENT BUILDINGS LARGER THAN 15,000 SQUARE FEET. THE PROGRAM OFFERS AN INCENTIVE TOWARD ENERGY MODELLING FEES AS WELL AS AN IMPLEMENTATION INCENTIVE BASED ON THE ELECTRICITY SAVINGS OF THE NEW BUILDING RELATIVE TO THE BUILDING CODE. ]**

Today's call should take about 15 minutes. Is this a convenient time to talk? Please be advised that this call may be recorded for quality assurance.

1. (Yes) [CONTINUE]
2. (No, later) [RESCHEDULE]
3. (No, refused) [THANK AND TERMINATE]

## A. Energy Modeller Profile

A1. To begin, what is your title and your role with your company?

A2. We would like to understand a bit more about your company's energy modelling business in Nova Scotia. Roughly what percentage of your energy modelling business in Nova Scotia is for buildings in the the following sectors <READ EACH BUILDING TYPE WHERE A1=YES>? **[TOTAL MUST EQUAL 100%]**

| Building type                  | % |
|--------------------------------|---|
| Residential multiunit ("MURB") |   |
| Commercial                     |   |
| Institutional and Government   |   |
| Industrial                     |   |
| Other                          |   |

98. Don't know

99. Refused

A3. And roughly what percentage of your company's modelling business in Nova Scotia is for buildings inside the Halifax Regional Municipality versus outside the Halifax Regional Municipality?

Inside HRM \_\_\_\_% Outside HRM \_\_\_\_% **[TOTAL MUST EQUAL 100%]**

98. Don't know

99. Refused

A4. What percentage of your Nova Scotia modelling business is for buildings?

1. ...less than 15,000 square feet in size \_\_\_\_

2. ...greater than 15,000 square feet in size \_\_\_\_%

**[TOTAL MUST EQUAL 100%]**

98. Don't know

99. Refused

A5. And finally, what percentage of your Nova Scotia models are for buildings that are electrically-heated versus gas-heated?

1. ... electricity\_\_\_\_%

2. ... gas\_\_\_\_%

3. ... Other [SPECIFY\_\_\_\_\_])

**[TOTAL MUST EQUAL 100%]**

98. Don't know

99. Refused

## B. Barriers to Participation and Motivations

B1. In your experience, why are some builders NOT completing an **energy model** for their building? **[DO NOT READ. MULTIPLE RESPONSE]**

1. (Cost – energy efficiency upgrades are too expensive)
2. (Cost – energy modeling is too expensive)
3. (Cost – developers or investors are not willing to pay for energy efficiency upgrades)
4. (Time – builders think the additional time for modelling will cause project delays)
5. (Builder awareness – builders are not aware of energy efficient design or technologies)
6. (Builder expertise – builders lack expertise to design or build energy efficient buildings)
7. (Builders are not aware of the benefits of energy modelling)
8. (Developers or investors do not request or prioritize energy efficiency)
9. (Builder believes meeting minimum energy efficiency code requirements is sufficient)
10. (Risk – Builder believes incorporating energy efficiency into building design is too risky)
11. (Project size may be too small to justify the additional time and cost of modelling)
96. Other: [SPECIFY \_\_\_\_\_]
98. Don't know
99. Refused

B2. And what are the reasons your customers complete an **energy model**? **[DO NOT READ. MULTIPLE RESPONSES]**

1. (Cost reduction – modeling can help identify cost-effective materials and systems)
2. (Code compliance – meeting minimum building energy code/energy performance requirements)
3. (Increased energy performance – builders want to construct buildings that exceed minimum energy performance requirements)
4. (Green building certification – builders seek green building certifications such as LEED or BREEM)
5. (Financial incentives and rebates from government and utilities)
6. (Increase long term investment value through more energy efficient design)
7. (Higher marketing value – energy efficient buildings result in lower operating costs for tenants)
8. (Higher marketing value – sustainability is an important selling point)
96. Other: [SPECIFY \_\_\_\_\_]
98. Don't know
99. Refused

B3. In your experience, what are the reasons builders choose NOT to design higher energy efficient buildings that exceed code requirements? **[DO NOT READ. MULTIPLE RESPONSES]**

1. (Cost – builders believe energy efficiency upgrades are too expensive)
2. (Time – builders believe higher performing buildings take longer to build)
3. (Investors or developers do not prioritize energy efficiency)
4. (Uncertain market value – builders are unsure the market will recognize the value added of higher performing buildings)
5. (Builder awareness – builders are not aware of energy efficient design or technologies)
6. (Builder expertise – builders lack expertise to design or build energy efficient buildings)
7. (Builders believe meeting minimum energy efficiency code requirements is sufficient)
8. (Uncertain energy costs – builders believe energy prices are too uncertain to justify investments in energy efficiency)
9. (Risk – Builder believes incorporating energy efficiency into building design is too risky)
96. Other: [SPECIFY \_\_\_\_\_])
98. Don't know
99. Refused

B4. What are the reasons builders decide to design higher energy efficient buildings that exceed the building code? **[DO NOT READ. MULTIPLE RESPONSES]**

1. (Lower building operating costs)
2. (Increase property value )
3. (Protection against rising energy costs)
4. (Gaining a competitive advantage in the market)
5. (Meet tenant or investor expectations for energy efficiency)
6. (Satisfy market demand for sustainable or green buildings)
7. (Access financing or incentives for high performing buildings)
8. (Improve building occupant comfort or satisfaction)
9. (Increase building durability)
10. (Meet government mandates and/or climate goals)
96. Other: [SPECIFY \_\_\_\_\_])
98. Don't know
99. Refused

## C. GHG Emissions & Electrification

- C1. Have you had discussions with your builder clients about reducing GHG emissions or about electrification?
1. Yes, reducing GHG emissions
  2. Yes, electrification
  3. No
  98. Don't know
  99. Refused
- C2. **[IF C1 = 1 OR 2]** What issues or concerns, if any, are top of mind among them? **[RECORD VERBATIM]**
- C3. In your opinion, how do these issues impact your clients' choices related to the energy performance of their new buildings? **[PROBE: less/more interest in energy efficiency, fuel choice (electric vs. gas heating)]** **[RECORD VERBATIM]**

## D. NECB 2020

- D1. In April 2025, Nova Scotia will adopt the National Energy Code of Canada for Buildings 2020 (NECB2020). Have you had discussions with your builder clients about NECB2020?
1. Yes
  2. No
  98. Don't know
  99. Refused
- D2. **[IF D1 = 1]** What issues or concerns, if any, are top of mind among them? **[RECORD VERBATIM]**
- D3. In your opinion, how does NECB2020 impact your clients' choices related to the energy performance of their new buildings? **[PROBE: more energy modelling, less/more interest in energy efficiency, fuel choice (electric or gas heating)]** **[RECORD VERBATIM]**

## E. Program Awareness and Participation

- E1. Have you ever heard of the New Construction program from Efficiency Nova Scotia?
1. Yes
  2. No
  98. Don't know
  99. Refused

- E2. **[IF E1 = 1]** How familiar are you with the New Construction program? Are you **[READ RESPONSES]** familiar with the program?
1. Very
  2. Somewhat
  3. Not very; or
  4. Not at all
  98. Don't know
  99. Refused
- E3. **[IF E1=1]** How did you hear of the New Construction program? Anywhere else? **[DO NOT READ. MULTIPLE RESPONSE]**
1. (Another modeller)
  2. (Efficiency Nova Scotia website)
  3. (Online – general)
  4. (Social media)
  5. (Through another Efficiency One)
  6. (Via a friend, acquaintance, or family member)
  7. (Radio ads)
  8. (Newspaper)
  9. (Efficiency newsletter - online/email)
  10. (TV ad)
  11. (Brochure/handout)
  12. (Special event like a home show)
  96. (Other [SPECIFY \_\_\_\_\_])
  98. (Don't know)
  99. (Refused)
- E4. **[IF NON-PARTICIPANT MODELLER and E1 = 1]** Why have you not been involved in the program? **[DO NOT READ. MULTIPLE RESPONSE]**
1. (Does not understand how program works)
  2. (Energy modelling incentives are too low)
  3. (Customers do not want to participate in the program)
  4. (Company staff lacks time to participate in program)
  5. (Heard negative feedback about program from other modelers)
  6. (Had negative experiences with similar programs in the past)
  96. (Other [SPECIFY \_\_\_\_\_])
  98. (Don't know)
  99. (Refused)

- E5. **[IF E1 = 1 AND NON-PARTICIPANT MODELLER]** Do you ever discuss the New Construction program to the builders you work with?
1. Yes
  2. No
  98. Don't know
  99. Refused
- E6. **[IF E5 = 1 AND NON-PARTICIPANT MODELLER]** Who typically initiates the discussions about the New Construction program? Is it **[READ]**?
1. You/your business bringing up the topic with the client
  2. The client bringing up the topic with you
  3. The idea arising from a discussion between your business and the client
  4. Someone from Efficiency Nova Scotia (e.g. Business Development Manager) suggesting it to you and your client.
  96. (Other [SPECIFY \_\_\_\_\_])
  98. (Don't know)
  99. (Refused)
- E7. **[IF NEW MODELLER]** Who initiated the discussion about participating in the New Construction program? Was it **[READ]**?
1. You/your business bringing up the topic with the client
  2. The client bringing up the topic with you
  3. The idea arising from a discussion between your business and the client
  4. Someone from Efficiency Nova Scotia (e.g. Business Development Manager) suggesting it to you and your client.
  96. (Other [SPECIFY \_\_\_\_\_])
  98. (Don't know)
  99. (Refused)

**[READ IF E1 = 2 OR E2=2 TO 4: EFFICIENCY NOVA SCOTIA'S NEW CONSTRUCTION PROGRAM PROVIDES SUPPORT FOR THE DESIGN AND CONSTRUCTION OF ENERGY EFFICIENT BUILDINGS LARGER THAN 15,000 SQUARE FEET. THE PROGRAM OFFERS AN INCENTIVE TOWARD ENERGY MODELLING FEES AS WELL AS AN IMPLEMENTATION INCENTIVE BASED ON THE ELECTRICITY SAVINGS OF THE PERFORMANCE OF THE NEW BUILDING RELATIVE TO THE BUILDING CODE.]**

- E8. What could Efficiency Nova Scotia do to support the building energy modelling industry in Nova Scotia? **[RECORD VERBATIM RESPONSE]**
96. (Don't know)
  99. (Refused)

- E9. What could the New Construction program do to encourage more participation among builders? **[DO NOT READ. MULTIPLE RESPONSE]**
1. (Increase incentives for energy modelling)
  2. (Increase incentive for my customers – for implementation/performance)
  3. (Speed-up the incentive payment process)
  4. (Clarify eligibility guidelines)
  5. (Make eligibility guidelines more flexible)
  6. (Allow gas-heated buildings)
  7. (Provide more technical support)
  8. (Improve communications and outreach)
  9. (Nothing)
  96. (Other [SPECIFY \_\_\_\_\_])
  98. (Don't know)
  99. (Refused)
- E10. Is there anything additional that Efficiency Nova Scotia could do to encourage participation specifically from the non-MURB market? What about the market outside of Halifax Metropolitan Area? **[RECORD VERBATIM RESPONSE for each]**
- a. Answer for encouraging non-MURB market: \_\_\_\_\_
  - b. Answer for encouraging market outside of Halifax: \_\_\_\_\_
  98. (Don't know)
  99. (Refused)
- E11. **[IF NEW MODELLER]** What additional support could Efficiency One offer to make your job easier when supporting clients in the New Construction program? **[RECORD VERBATIM RESPONSE for each]**
98. (Don't know)
  99. (Refused)

**END**

Those are all the questions I have for you today. Thank you for your time and the valuable feedback you have provided.

## APPENDIX X

# New Construction Program Manager and Business Development Manager Interview Guide

## GUIDE FOR INTERVIEWS WITH Program staff and BDMs

**Table 7: Overview of Data Collection Activity**

| Descriptor                      | This Instrument                                                                                                  |
|---------------------------------|------------------------------------------------------------------------------------------------------------------|
| Instrument Type                 | Semi-directed in-depth interview                                                                                 |
| Estimated Time to Complete      | 45 min for Program Manager, 45 min for BDM                                                                       |
| Target Audience                 | E1 program staff: <ul style="list-style-type: none"> <li>› Commercial NC PM</li> <li>› Commercial BDM</li> </ul> |
| Expected Number of Completions  | 2                                                                                                                |
| Contact List Source             | Efficiency One                                                                                                   |
| Fielding Firm                   | Econoler                                                                                                         |
| Estimated Timeline for Fielding | October 2024                                                                                                     |

**Table 8: Research Objectives and Questions**

| Research objective                                      | Research Questions                                                                           | Section/Question # |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------|--------------------|
| › Explore opportunities to expand program participation | › How has program participation changed over time?                                           | › Section E        |
|                                                         | › Are projects outside of Halifax area underrepresented in New Construction?                 | › E1-E3            |
|                                                         | › What are the motivations and barriers for non-MURB builders to participate in the program? | › E4-E5            |
|                                                         | › What actions could be taken by the program to target more non-MURB participants?           |                    |
|                                                         | › What is E1's current relationship with modelers involved in the program?                   | › Section D        |
|                                                         | › How could the number of energy modelers involved be increased?                             |                    |
| › Update program service logic                          | › What are the barriers to program participation?                                            | › Section B        |
|                                                         | › Does the current program logic align with participant barriers?                            | › Section C        |

## A. Respondent Involvement in the Program

- A1. [FOR BDM Interviews] To begin, please tell me about your role as a **< Business development Manager>** as it relates to Custom New Construction program services?

## B. Motivation and Barriers

- B1. In your experience, what prevents customers from building high-efficiency buildings in the absence of support from E1?
- B2. How do you describe the value or benefits of the Custom New Construction Program to potential participants?
- B3. What are the most common motivations for participants to participate in the program?
- B4. In your opinion, what is the primary barrier to participating in the program? Any others? Do you think that varies depending on the building/participant type or regionally?

## C. Program logic model

- C1. [PROGRAM MANAGER ONLY] Can you walk through the program logic model, starting with what you see as the main market barriers to efficient new buildings and how the program addresses those barriers?.

## D. Market actors

- D1. How do you work with energy modellers/consultants for New Construction? **[Probe: Are they a source of projects?]**
- D2. How would you describe E1's current relationship with energy modellers?
- D3. Do you have any suggestions for improving the program's relationship with energy modellers?
- D4. In the past projects in the New Construction program were primarily modelled by one energy modeller. Do you think that is an issue for participation in the program? Why do you say that?
- D5. What, if anything, have you done to increase the number of modellers participating in the program?

## E. Market and program evolution

- E1. How has the new construction market evolved in Nova Scotia the last few years, both inside and outside of the Halifax Municipal Region?
- E2. In your opinion, is the program under-represented in areas outside of Halifax? Why do you say that?
- E3. What could be done to attract more participation outside of the Halifax Metropolitan Area?

- 
- E4. In your opinion, is the program under-represented in non-MURBs? Why do you say that?
  - E5. What could be done to attract more participation outside of the MURB market?
  - E6. Can you describe, overall, how the program has evolved during the last few years?
  - E7. Have your customers discussed decarbonization or electrification with you? If yes, what are their concerns?
  - E8. In your opinion, how do participant's decarbonization or electrification objectives impact participation in New Construction? [PROBE: more interest, different measures]?
  - E9. Have your customers discussed NECB2020 with you? If yes, what are their concerns? Any impact on participation in New Construction?

## **F. Challenges and Opportunities**

- F1. Overall, what is the main strength of the New Construction program?
- F2. What is the main challenge of the New Construction program?
- F3. What feedback have you heard from participants about the New Construction program?
- F4. Are there any other challenges with the program or delivery that we haven't discussed?
- F5. Are there any changes to the program you are interested in for the future?
- F6. Do you have any other suggestions for program improvements?
- F7. What should the program stop doing?
- F8. What should the program start doing?

## **G. Program evaluation**

- G1. [Program manager only] We will look at Commercial new construction program eligibility criteria in other jurisdictions to inform the process evaluation. Are there specific jurisdictions you recommend we consider?

Those are all the questions I have for you today. Would you like to add anything else regarding the New Construction program?

# APPENDIX XI

## New Construction Energy Model Review Protocol

### Project Review Protocol

Custom New Construction  
Efficiency Nova Scotia  
Simulation Model Review Protocol

#### 1. General Information

Review Date: \_\_\_\_\_ Contact Name: \_\_\_\_\_  
Project ID: \_\_\_\_\_ Contact Title: \_\_\_\_\_  
Project Type: \_\_\_\_\_ Contact Phone: \_\_\_\_\_  
Project Status: \_\_\_\_\_ Email: \_\_\_\_\_  
Project Name: \_\_\_\_\_  
Address: \_\_\_\_\_

#### Project Energy Efficiency Measure(s)

Information Sent by E1 Sufficient to Review the Project? \_\_\_\_\_ (Y/N)

Call or Virtual Visit Needed \_\_\_\_\_ (Call/Visit)

List of people participating to the virtual visit/call: \_\_\_\_\_  
\_\_\_\_\_

#### 2. Facility Operation Schedules

*These data should be asked prior the virtual visit by email or phone to the final beneficiary of the building or found in documentation sent by E1*

People/ Document giving information \_\_\_\_\_  
\_\_\_\_\_

**Facility Description:** \_\_\_\_\_ Outline a quick description of the facility and its primary operation/purpose.

NOTE: PC Users "Alt+Enter" for new line in cell. MAC Users "CMD+Option+Enter".

**Facility Annual Schedule:**

*Gather info for each occupancy schedule reported by the site contact as occupancy could vary for each section of the facility. Use additional lines if necessary. Ensure info is for a typical year (non-COVID).*

|  |
|--|
|  |
|--|

**HVAC System Operation Schedule:**

*Gather info for each HVAC system.*

#### 4. Adjustments to Energy Model per Measure

The reviewer must verify the model following guidance defined in the tab "Modelling Review Checklist".

| Description from project documentation |  |
|----------------------------------------|--|
| Virtual visit, call or document        |  |
| As modeled by participant              |  |
| Changes to model by Econoler           |  |

| Description from project documentation |  |
|----------------------------------------|--|
| Virtual visit, call or document        |  |
| As modeled by participant              |  |
| Changes to model by Econoler           |  |

| Description from project documentation |  |
|----------------------------------------|--|
| Virtual visit                          |  |
| As modeled by participant              |  |
| Changes to model by Econoler           |  |

| Description from project documentation |  |
|----------------------------------------|--|
| Virtual visit, call or document        |  |
| As modeled by participant              |  |
| Changes to model by Econoler           |  |

| Description from project documentation |  |
|----------------------------------------|--|
| Virtual visit                          |  |
| As modeled by participant              |  |
| Changes to model by Econoler           |  |

## 5. Simulation Outputs

Name of the simulation file

|          | EOne | Evaluator |
|----------|------|-----------|
| Basecase |      |           |
| Proposed |      |           |

### Energy Consumption (kWh)

|                  | EOne     |          | Evaluator |          |
|------------------|----------|----------|-----------|----------|

| Line Loss Factor Used |  |
|-----------------------|--|

## 7. Summarize Adjustments to Energy, Demand & Diversity Factor

# Modelling Review Checklist

## Reminder of Evaluation Goals and Key Principles

While developing the checklist, the Evaluator kept in mind the key evaluation goals and the five guiding principles presented in the 2020-2022 Overall Strategic Evaluation Plan.

Notably for New Construction, Principle 4 states that:

For some complex program services (e.g. Custom New Construction), the Evaluator thoroughly reviews measures that contribute the most savings to a project but does not comprehensively review the entire model or measurement and verification (M&V) procedures. Thus, the evaluation review should not be interpreted as vetting all modelling or M&V practices.

## Simulation Model Review Checklist

The checklist consists of the six main items below. This checklist should be considered as general guidelines. Simulation model reviews are treated on a case by case basis and other items may be considered depending on the building type, complexity of the HVAC systems, energy efficiency measures installed etc.

### 1 Results General Overview

- Check savings (in %) for each end use and identify where the major savings lie. Crosscheck with the energy efficiency measure list to validate if the savings claimed make sense.
- Verify GJ/m<sup>2</sup> and check benchmarking data to verify if energy intensity is normal based on the type of building. Pay attention to differences in buildings that can explain discrepancies (e.g. two apartment buildings with the same area will not have a comparable GJ/m<sup>2</sup> if only one of them has an underground parking).

### 2 Envelope Review

- Check envelope resistance value (wall/fenestration/roof/etc.) and validate with shop drawings and construction details. Make sure that effective R/RSI – U/USI values are used in the simulation.
- Pay particular attention to curtain walls. Although the nominal insulation value may be high (up to R15-20), the effective value rarely exceeds R8 because of the effect of the frame.
- Verify fenestration-to-wall ratio (%) in the proposed model. If the ratio is above baseline allowance, validate that the reference model ratio has been reduced to maximum allowance.
- Validate that the values used for the reference are in accordance with the specifications of the code used.

### 3 Parametrization and Zoning

- For buildings with a repetitive storey pattern, if the “Copy” function is used, the modeller often forgets to check the “Over conditioned space” option, which may create an “exterior floor”.
- Verify the zoning to make sure it is appropriate.

### 4 Loads and Schedules

- Validate occupancy and plug-load values according to NECB.
- Validate lighting loads by spot-checking installed lighting power in random rooms vs. electrical plans and shop drawings.
- Validate domestic hot water (DHW) loads according to the guideline developed by EfficiencyOne for DHW consumption values.
- Validate that the schedules used are typical for the type of building modelled.

## 5 HVAC Systems

This section can be very complex, depending on the building modelled, so the following should be considered as general guidelines.

Please refer to E1 White Paper - Baseline HVAC System in MURBs for MURBS

- Validate that all HVAC inputs concord with shop drawings.
- In the case of a dedicated outside air system, pay attention to how it has been modelled.
- Validate that the systems selected are in accordance with the specification of the code used (type of system, efficiency, sizing) for the reference building.
- Carefully read the operating sequence and verify that the HVAC systems operate accordingly.
- Take special care to validate the modelling of energy efficiency measures.
- Make sure that the air flow (cfm) of installed systems match the cfm modelled (reference and proposed) for fresh air.
- Be on the lookout if known bugs/miscalculations in the modelling software are present due to the system types used within the model. If present, see if the energy modeller can address them.

## 6 External Calculations

- Review external calculations, if any.

## APPENDIX XII

### New Construction Algorithm for Free-Ridership Calculation

**Table 1: Participant Interview Questionnaire and Free-ridership Algorithm**

| Question |                                                                                                                                                                                                  | Answer                                                                                                                                                                                                                                          | Score                                                                                                                                                                                                                        |

## APPENDIX XIII

### New Construction Tracking Sheet Audit

This appendix presents the main results of the tracking sheet audit performed by the Evaluator, which was aimed at:

- › Verifying that all data fields required for the evaluation were included and filled out in the tracking sheet submitted by E1
- › Ensuring that tracked results were accurate by:
  - › Verifying that parameters used to calculate program results (gross and net energy and peak demand savings at the generator) were consistent with previous evaluation results
  - › Validating that all calculation steps were performed consistently

Table 1 presents the corrected tracked savings resulting from all changes made by the Evaluator.

**Table 1: 2024 Custom Corrected Tracked Savings**

| Program Component Result                | Tracked by E1 |      | Corrected Tracked Value |      | Relative Difference |
|-----------------------------------------|---------------|------|-------------------------|------|---------------------|
|                                         | Value         | Unit | Value                   | Unit |                     |
| Gross Energy Savings – at the Generator | 20.855        | GWh  | 20.900                  | GWh  | 0.22%               |
| Gross Demand Savings – at the Generator | 3.984         | MW   | 3.992                   | MW   | 0.19%               |
| Net Energy Savings – at the Generator   | 14.390        | GWh  | 14.421                  | GWh  | 0.22%               |
| Net Demand Savings – at the Generator   | 2.749         | MW   | 2.754                   | MW   | 0.19%               |

There were no substantial differences between the tracked and corrected tracked energy and demand savings. The minor changes were due to adjustments made to line loss factors.

## APPENDIX XIV

### Custom 2024 Recommendations

This appendix summarizes all the recommendations made by the Evaluator as part of the Custom evaluation.

| Section           | Recommendations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Executive Summary | 2024 New Construction Recommendation #1: Review the demand savings script used for projects modelled in eQuest to ensure accurate results and favour an approach that can be applied consistently across a variety of modelling software.                                                                                                                                                                                                                                                                                                            |
| Executive Summary | 2024 New Construction Recommendation #2: Amend section 7.10 of the New Construction program guide to require M&V for large industrial New Construction projects.                                                                                                                                                                                                                                                                                                                                                                                     |
| Executive Summary | New Construction Recommendation #3: Investigate the impact of increasing modelling incentives (the share of modelling costs covered as well as the incentive cap) on the service.                                                                                                                                                                                                                                                                                                                                                                    |
| Executive Summary | New Construction Recommendation #4: Endeavour to recruit new energy modellers through targeted outreach; modellers put a premium on networking opportunities with builders.                                                                                                                                                                                                                                                                                                                                                                          |
| Executive Summary | New Construction Recommendation #5: Consider collaborating with educational institutions and professional associations for energy modelling to build a stronger pipeline of qualified and engaged energy modellers across Nova Scotia.                                                                                                                                                                                                                                                                                                               |
| Executive Summary | New Construction Recommendation #6: The program should increase targeted outreach and educational activities for builders and energy modellers related to the code shift and its impacts, particularly those involving technologies (including electrification), costs, and energy efficiency improvements. By providing practical guidance on meeting new requirements and exceeding them with the program's support, the program can position itself as a valuable resource while increasing program awareness and encouraging more participation. |
| Executive Summary | New Construction Recommendation #7: Review the program guidelines and update to align with NECB 2020, which will be adopted in April 2025.                                                                                                                                                                                                                                                                                                                                                                                                           |
| Executive Summary | New Construction Recommendation #8: Investigate aligning implementation incentives with NECB 2020 Tiers. Such alignment would need to consider the phased-in adoption of NECB 2020 Tiers 1–3 over 2025-29.                                                                                                                                                                                                                                                                                                                                           |
| Executive Summary | New Construction Recommendation #9: E1 should update the Custom New Construction logic model to document and address current barriers and update the theory of change to include all activities being carried out to address these barriers.                                                                                                                                                                                                                                                                                                         |

## APPENDIX XV

### SEM Tracking Sheet Audit

This appendix presents the main results of the tracking sheet audit performed by the Evaluator, which was aimed at:

- › Verifying that all data fields required for the evaluation were included and filled out in the tracking sheet submitted by EfficiencyOne (E1)
- › Ensuring that tracked results were accurate by:
  - › Verifying that parameters used to calculate program results (gross and net electrical energy and peak demand savings at the generator) were consistent with previous evaluation results
  - › Validating that all calculation steps were performed consistently

Table 1 presents the corrected tracked savings resulting from all changes made by the Evaluator.

**Table 1: 2024 SEM Corrected Tracked Savings**

| Program Component Result                   | Tracked by E1 |      | Corrected Tracked Value |      | Relative Difference |
|--------------------------------------------|---------------|------|-------------------------|------|---------------------|
|                                            | Value         | Unit | Value                   | Unit |                     |
| Gross Energy Savings at the Generator      | 4.474         | GWh  | 4.480                   | GWh  | 0.12%               |
| Gross Peak Demand Savings at the Generator | 0.536         | MW   | 0.537                   | MW   | 0.18%               |
| Net Energy Savings at the Generator        | 4.474         | GWh  | 4.480                   | GWh  | 0.12%               |
| Net Peak Demand Savings at the Generator   | 0.536         | MW   | 0.537                   | MW   | 0.18%               |

The minor changes in electrical energy and peak demand savings were due to adjustments made to line loss factors.

Page 10 of 10

Phone interviews or site visits were conducted after a review of EfficiencyOne digital project files. As part of the project file review, the Evaluator noted questions to be answered by participants during the interview or the site visit, and the protocol was also used to consign their answers.

|                                      |                          |       |                          |                |  |
|--------------------------------------|--------------------------|-------|--------------------------|----------------|--|
| Interview/Site Visit Date:           |                          | Team: |                          | Contact Name:  |  |
| Project ID:                          |                          |       |                          | Contact Title: |  |
| NSPI Rate Code:                      |                          |       |                          | Phone:         |  |
| Company Name:                        |                          |       |                          | Email:         |  |
| Address:                             |                          |       |                          |                |  |
|                                      |                          |       |                          |                |  |
| List of people met during the visit: |                          |       |                          |                |  |
|                                      |                          |       |                          |                |  |
| Person(s) Responsible for SEM:       |                          |       |                          |                |  |
|                                      |                          |       |                          |                |  |
| Type of building:                    | Commercial/institutional |       | Industrial/manufacturing |                |  |
|                                      | Municipal                |       | Other (specify)          |                |  |

|                                                                                |  |
|--------------------------------------------------------------------------------|--|
| Number of years in program (1st, 2nd, et.c)                                    |  |
| What was the savings quantification approach last year (bottom-up or top-down) |  |
| Last year measure list                                                         |  |
| Last year savings                                                              |  |

#### 4. Impact Evaluation & Savings Adjustments

|                                    |  |
|------------------------------------|--|
| Reporting period                   |  |
| Overall M&V approach and reasoning |  |

Which measures were implemented and do they generate incremental energy and demand savings?

| Measure | Implementation date | Expected to generate incremental savings for this year? | Time period when generating savings | PCF |
|---------|---------------------|---------------------------------------------------------|-------------------------------------|-----|
|         |                     |                                                         |                                     |     |
|         |                     |                                                         |                                     |     |
|         |                     |                                                         |                                     |     |
|         |                     |                                                         |                                     |     |
|         |                     |                                                         |                                     |     |

#### Bottom-up Approach

| Measure 1                                                        | Notes |
|------------------------------------------------------------------|-------|
| Measure Description                                              |       |
| Validation of the measure (is it installed and operational?)     |       |
| Savings calculation approach - What is it and is it appropriate? |       |
| What is the baseline and is it appropriate?                      |       |
| Are savings annualized for a standard year?                      |       |
| Are IE considered?                                               |       |
| EUL                                                              |       |

|                         |        | Tracked | Evaluated | % of Tracked savings |  |  |  |
|-------------------------|--------|---------|-----------|----------------------|--|--|--|
| Electricity Savings     | kWh/yr |         |           |                      |  |  |  |

## APPENDIX XVII

### SEM Detailed Project Review Adjustments

**Table 1: 2024 SEM Electrical Energy Savings Adjustments**

| Project      | Tracked Savings (kWh) | Evaluated Savings (kWh) | Adjustment Ratio | Explanation for Adjustment                                                                                                                                                                                                                                                                                                                    |
|--------------|-----------------------|-------------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1            | 1,186,033             | 1,186,033               | 1.000            | None.                                                                                                                                                                                                                                                                                                                                         |
| 2            | 298,525               | 298,525                 | 1.000            | None.                                                                                                                                                                                                                                                                                                                                         |
| 3            | 277,960               | 276,378                 | 0.994            | Electrical energy savings were adjusted from 277,960 to 276,378 kWh to correct for two minor calculation errors.                                                                                                                                                                                                                              |
| 4            | 111,321               | 111,321                 | 1.000            | None.                                                                                                                                                                                                                                                                                                                                         |
| 5            | 76,574                | 76,487                  | 0.999            | The electrical energy savings were adjusted based on a calculation error made in the energy savings calculation for energy conservation measure (ECM) 69. This adjustment increased the daily electrical energy savings for ECM 69 from 296 kWh/day to 317 kWh/day, which were then subtracted from the site-level electrical energy savings. |
| 6            | 1,775,743             | 1,775,743               | 1.000            | None.                                                                                                                                                                                                                                                                                                                                         |
| 7            | 542,829               | 542,829                 | 1.000            | None.                                                                                                                                                                                                                                                                                                                                         |
| <b>Total</b> | <b>4,268,985</b>      | <b>4,267,316</b>        | <b>1.000</b>     |                                                                                                                                                                                                                                                                                                                                               |

**Table 2: 2024 SEM Peak Demand Savings Adjustments**

| Project      | Tracked Savings (MW) | Evaluated Savings (MW) | Adjustment Ratio | Explanation for Adjustment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| 2            | 0.0344               | 0.0344                 | 1.000            | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 3            | 0.0544               | 0.0530                 | 0.994            | Peak demand savings were adjusted from 54.4 kW to 53.0 kW due to minor spreadsheet errors and to account for the annual winter maintenance outage.                                                                                                                                                                                                                                                                                                                                                                                              |
| 4            | 0                    | -0.0012                | -                | Peak demand savings were updated. The change reflects an increase in peak demand resulting from scrap materials being processed during weekdays as opposed to the baseline condition when scrap was processed on weekends.                                                                                                                                                                                                                                                                                                                      |
| 5            | 0.0087               | 0.0262                 | 3.007            | Peak demand savings were increased based on a review of hourly interval data. When calculating 8.7 kW as the peak demand savings, the electrical energy savings were averaged across 8,760 hours/year. The Evaluator reviewed the actual electrical energy savings achieved between 5 p.m. and 7 p.m. on non-holiday weekdays between December 1 and February 28 and adjusted the peak demand savings accordingly.                                                                                                                              |
| 6            | 0.2027               | 0.2027                 | 1.000            | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 7            | 0.0766               | 0.0627                 | 0.819            | Updates to the peak demand savings were made to ECM 85 and ECM 95 to better reflect that the interval data used in both measures to calculate the peak demand savings does not fully align with the non-holiday weekday or December to February timeframe. Therefore, a conservative approach to estimating these savings assumed the use of a peak coincident factor (PCF) of 1. For ECM 85, this resulted in peak demand savings increasing from 6.9 kW to 7.5 kW while, for ECM 95, the peak demand savings changed from 46.6 kW to 32.1 kW. |
| <b>Total</b> | <b>0.5122</b>        | <b>0.5132</b>          | <b>1.002</b>     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## APPENDIX XVIII

### SEM 2024 Recommendations

---

The Evaluator made no recommendations as part of the 2024 SEM evaluation.

## DEFINITIONS

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Accuracy</b>                           | Reflects the proximity of measurements to the true value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Adjustment ratio</b>                   | The ratio of evaluated results to tracked results. This ratio expresses the adjustment made to tracked savings or other tracked values such as effective useful life.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Available Demand Response Capacity</b> | The capacity which is available to NSP to reduce system peak demand. This capacity is calculated based on the first two hours of all events called between December and February, excluding weekends and holidays. If an event is shorter than two hours, only the first hour is used to measure the available DR capacity. Available DR capacity is evaluated on a per-participant basis, based on the average demand reduction observed for each event that the participant was scheduled to participate in. E1's total available DR capacity is the sum of each participant's available DR capacity. |
| <b>Baseline</b>                           | To determine gross savings, a baseline (or base case) is established providing detailed information about the reference (e.g. pre-existing or standard) measure or equipment chosen to be compared with the efficient measure or equipment. For the reference measure or equipment, the baseline may include such information as the hours of operation, wattage, and base consumption.                                                                                                                                                                                                                 |
| <b>Bias</b>                               | Systematic deviations of measurements from the true value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Billing calibration</b>                | An activity that consists of adjusting the expected energy savings based on the relative difference between the results of energy simulations and the actual energy consumption of a building or system.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Confidence interval</b>                | The estimated range of values that is likely to include unknown population parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Demand response</b>                    | Demand response measures generate savings in the form of available capacity or load reduction in response to events called by the electric utility (Nova Scotia Power) to reduce the load at strategic moments. These events can be called at any time and for any duration, although they are usually called for one to four hours during peak periods.                                                                                                                                                                                                                                                |
| <b>Displaced wattage</b>                  | The displaced wattage is defined as the difference between the wattage values of the baseline equipment or product and the efficient equipment or product.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>EnerGuide rating</b>                   | An EnerGuide (official brand of Natural Resources Canada) rating is a standard measure of home energy performance. It is a measure of the efficiency of the building only and does not take into account occupant behaviour. It shows how energy efficient a home is through modelled home heat losses based on several factors including building envelope characteristics, heated volume, heating systems, and air leakage.                                                                                                                                                                           |
| <b>Effective useful life</b>              | The period a measure is expected to be in service and provide both energy and peak demand savings. This value combines equipment life and measure persistence, which includes factors such as business turnover or early retirement.                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Equipment life</b>                     | The number of years installed equipment will operate before it fails.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                                         |                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Equivalent CO2</b>                   | A unit of measurement indicating the amount of carbon dioxide to which various kinds of emitted greenhouse gases are equivalent in terms of warming effects. In this report, gas global-warming potential is estimated over a timescale of 100 years.                                                                |
| <b>Equivalent effective useful life</b> | The number of years by which the first-year savings estimate is multiplied to obtain lifetime energy savings. This value takes into account variations in annual energy savings throughout the effective useful life due to increased baselines.                                                                     |
| <b>Evaluated savings</b>                | Gross and net energy or peak demand savings calculated by the Evaluator using the parameters (unitary savings values, installation rates, interactive effects, net-to-gross ratios, etc.) validated or measured during the evaluation process. Unless otherwise specified, evaluated savings are first-year savings. |
| <b>Evaluation plan</b>                  | The evaluation plan summarizes the program description, objectives, base cases, documentation, evaluation methodology, budget, and schedule.                                                                                                                                                                         |
| <b>First-year savings</b>               | The first full year of energy or peak demand savings generated by an energy efficiency measure.                                                                                                                                                                                                                      |
| <b>Free-ridership</b>                   | Percentage of gross savings attributable to participants who would have implemented the same or similar energy efficiency measures, with no change in timing, in the absence of the program.                                                                                                                         |
| <b>Gross savings</b>                    | Change in energy consumption and/or demand that results directly from program-related actions taken by participants in an efficiency program regardless of why they participated.                                                                                                                                    |
| <b>Induced consumption</b>              | Energy consumption of appliances that would have been unplugged and not replaced by participants in the absence of the program.                                                                                                                                                                                      |
| <b>Interactive effects</b>              | Effects on the energy consumption of other systems in a building (such as heating and cooling) due to the installation of an energy-efficient measure.                                                                                                                                                               |
| <b>In-service rate</b>                  | The proportion of incentivized products that are installed and operating. This rate is usually applied to programs through which rebates are offered in-store and products are likely to be stored for a certain period before being installed, such as LED lamps.                                                   |
| <b>Installation rate</b>                | The proportion of incentivized products reported as installed and that remain installed and operating at the time of evaluation. This rate is usually applied to direct install or mail-in rebate programs through which measures are expected to be installed immediately at the time of participation.             |
| <b>Lifetime energy savings</b>          | The energy savings that occur over the lifetime of an energy efficiency measure. Lifetime energy savings account for a measure's effective useful life and any increase in the baseline efficiency level (which reduces attributable annual savings) over its lifetime.                                              |
| <b>Line loss factor</b>                 | The multiplier to convert savings at the customer meter to savings at the utility generator. It accounts for the electrical losses of the transmission and distribution system.                                                                                                                                      |
| <b>Margin of error</b>                  | The amount of random sampling error.                                                                                                                                                                                                                                                                                 |
| <b>Market effects</b>                   | The impact of a program on the market (in terms of product availability, practices, and prices) that extends beyond changing program participant behaviours. This includes spillover among non-participants.                                                                                                         |

|                                 |                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Net savings</b>              | Energy or peak demand savings that can be reliably attributed to a program. This includes effects such as free-ridership and spillover that negatively or positively affect the savings attributable to a program.                                                                                                                           |
| <b>Net-to-gross ratio</b>       | The ratio of net energy savings to gross energy savings.                                                                                                                                                                                                                                                                                     |
| <b>Non-sampling error</b>       | Errors arising during all survey activities other than sampling. Non-sampling errors tend to lead to bias in measurements and are very difficult to quantify.                                                                                                                                                                                |
| <b>Peak coincidence factor</b>  | The percentage of measure demand savings that coincide in time with the annual peak demand of the entire electricity system.                                                                                                                                                                                                                 |
| <b>Peak demand savings</b>      | The demand savings that coincide in time with the expected annual peak demand period of the entire electricity system. For industrial participants on an interruptible rate, peak demand savings may include savings on non-firm loads, i.e. loads that may be interrupted when Nova Scotia Power's 10-minute reserve is low.                |
| <b>Precision</b>                | The extent to which repeated measurements agree with one another.                                                                                                                                                                                                                                                                            |
| <b>Random sampling error</b>    | An error in measurement because measurements are taken from a subset of the population and not the entire population.                                                                                                                                                                                                                        |
| <b>Realization rate</b>         | The ratio of evaluated savings to tracked savings.                                                                                                                                                                                                                                                                                           |
| <b>Sample size</b>              | The number of observations or replicates included in a statistical sample.                                                                                                                                                                                                                                                                   |
| <b>Secondary market impacts</b> | Energy consumption of appliances that would have been transferred to the secondary market if said appliances had not been retired.                                                                                                                                                                                                           |
| <b>Spillover</b>                | Savings attributable to participants who continue to implement the energy efficiency measure introduced by a program after participating in it once, without participating in the program a second time.                                                                                                                                     |
| <b>Tracked savings</b>          | Gross and net savings calculated based on various parameters such as number of participants or units installed or sold, unitary savings values, installation rates, interactive effects, and net-to-gross ratios. Those parameters, except the number of participants or units installed or sold, are obtained from the previous evaluation. |
| <b>Unitary savings</b>          | Energy or peak demand savings established on a unitary basis. A unit can either be a product (e.g. an 8 W LED lamp), a capacity (e.g. one-tonne capacity of an air-source heat pump), or a participant (e.g. one participant taking part in a behaviour-based program).                                                                      |

# EXECUTIVE SUMMARY

This report presents the 2024 Demand-Side Management (DSM) results of the Direct Installation program administered by EfficiencyOne (E1). This program is comprised of the Small Business Energy Solutions (SBES) program component. SBES offers incentives and resources to encourage Nova Scotia's small businesses to make energy efficiency upgrades to their facilities.

## Evaluation Approach

The purpose of the 2024 evaluation was to calculate gross and net results of the program components, namely electrical first-year and lifetime energy savings, peak demand savings, as well as avoided greenhouse gas (GHG) emissions. Table 1 summarizes the types of evaluations conducted and the corresponding methodology.

**Table 1: Summary of 2024 Direct Installation Program Evaluation**

| Program Component               | Evaluation Type |         |        | Methodology                                                                                                                                                                                                                                                                                                                       |

## Program Performance

Table 2 presents the participation levels, net-to-gross ratios (NTGRs), evaluated gross and net savings at the generator, annual GHG emission reductions, as well as effective useful life (EUL) values for the Direct Installation program.

**Table 2: Overall 2024 Direct Installation Participation and Evaluated Savings<sup>1</sup>**

|                                                                                                                      | Participation Level |               | Gross Savings |                  | NTGR* | Net Savings |                  |

| Peak Demand Savings                                                                                                  |                     |               | 2.679         | MW               | 0.80  | 2.155       | MW               |
| Annual GHG Emission Reductions                                                                                       |                     |               | 6,356         | Tonnes of CO2 eq | 0.81  | 5,125       | Tonnes of CO2 eq |
| EUL                                                                                                                  |                     |               | 16.4          | Years            |       | 16.4        | Years            |
| * The average NTGR values presented in this table correspond to the ratios of net savings to gross savings for SBES. |                     |               |               |                  |       |             |                  |

<sup>1</sup> The results presented in this table include savings for SBES and the CDI pilot.

<sup>2</sup> 741 of the 61,664 units rebated were CDI Pilot projects.

Direct Installation aimed to achieve 10.592 GWh of net electrical energy savings and 2.558 MW of net peak demand savings at the generator in 2024. The program slightly exceeded the planned net electrical energy savings target, but did not meet the planned net peak demand savings target.

## SBES Findings and Recommendations

This subsection presents the key findings from the SBES evaluation.

**2024 SBES-Finding:** SBES surpassed its net electrical energy savings by 2% and fell short of its net peak demand savings target by 16%.

**2024 SBES-Finding:** The evaluated net electrical energy savings and peak demand savings determined by the Evaluator were higher than the net savings tracked by E1.

**2024 SBES-Finding:** Participation in SBES, in terms of units rebated, increased by 53% in 2024 compared to 2023 levels. The DIY path remained the most popular, accounting for 98% of all units rebated. The units rebated through the CDI Pilot decreased by 48% in 2024 compared to 2023 levels.

**2024 SBES-Finding:** Based on the results from a survey of 30 businesses, non-participant spillover was found to be nil.

## Program Tracked and Evaluated Savings

Table 3 below compares E1 tracked energy and peak demand savings compared to evaluated savings at the generator. It also includes the realization rate, which is the ratio of evaluated net savings to tracked net savings, for both energy savings and peak demand savings. The NTGRs are also presented and correspond to the rounded averages obtained by dividing net savings by gross savings, which explains why the NTGR values are different from those presented in other sections.

**Table 3: Comparison of 2024 SBES Tracked and Evaluated Savings at the Generator<sup>3</sup>**

|                       | Gross Savings |      | NTGR | Net Savings |      | Realization Rate |
|-----------------------|---------------|------|------|-------------|------|------------------|
|                       | Value         | Unit |      | Value       | Unit |                  |
| Energy Savings        |               |      |      |             |      |                  |
| Tracked Savings by E1 | 12.936        | GWh  | 0.81 | 10.426      | GWh  | 104%             |
| Evaluation Results    | 13.459        | GWh  | 0.81 | 10.854      | GWh  |                  |
| Peak Demand Savings   |               |      |      |             |      |                  |
| Tracked Savings by E1 | 2.521         | MW   | 0.81 | 2.033       | MW   | 106%             |
| Evaluation Results    | 2.679         | MW   | 0.80 | 2.155       | MW   |                  |

<sup>3</sup> The results presented in this table include savings for SBES and the CDI Pilot.

## INTRODUCTION

EfficiencyOne (E1), an independent, non-profit organization, is responsible for helping Nova Scotians improve the energy efficiency of their homes and workplaces by designing, marketing, and delivering demand-side management (DSM) for Nova Scotians. E1 provides energy efficiency, demand response and carbon mitigation services through the Efficiency Nova Scotia (ENS) franchise. Regulatory oversight of its DSM activities is provided by the Nova Scotia Utility and Review Board (NSUARB). E1 receives funding for its electricity DSM activities from Nova Scotia Power (NS Power) ratepayers.

E1 has a DSM portfolio of three residential programs, three business, non-profit, and institutional (BNI) programs, and one demand response (DR) program that are marketed to Nova Scotians through the ENS franchise. Each program has one or more program components. Econoler was commissioned by E1 to evaluate E1's 2024 DSM program portfolio.

This evaluation report relates to the Direct Installation program, which is comprised of a single component: Small Business Energy Solutions (SBES). Table 4 below lists the Direct Installation program component and the type of evaluation conducted in 2024. A condensed impact evaluation involves using some or all of the previous year's impact evaluation parameters, such as unitary savings values, adjustment ratios, installation rates, and net-to-gross ratios (NTGRs) to provide evaluated results.

**Table 4: Type of Evaluation Conducted for SBES, 2024**

| Program             | Program Component | 2024    |        |           |
|---------------------|-------------------|---------|--------|-----------|
|                     |                   | Process | Market | Impact    |
| Direct Installation | SBES              | -       | -      | Condensed |

For each program, the Evaluator prepared a DSM evaluation report presenting key findings, electrical first-year and lifetime energy savings, peak demand savings, and avoided greenhouse gas (GHG) emissions.<sup>4</sup>

<sup>4</sup> Unless specified otherwise, energy savings refer to first-year energy savings rather than lifetime energy savings throughout this report.

# 1 SBES Overview

This section describes the Small Business Energy Solutions (SBES) program component, follows up on past evaluation recommendations, and provides an overview of participation history.

## 1.1 SBES Description

SBES offers incentives and resources to Nova Scotia small businesses to encourage them to make energy efficient upgrades in their facilities. To be eligible, businesses must annually consume less than 600,000 kWh<sup>5</sup> in electricity. Businesses with electricity consumption higher than this limit are directed toward the E1 Custom or Business Energy Rebates program components. SBES offers on-bill financing for eligible businesses provided they are NS Power customers and their accounts are in good standing.

SBES offers two paths for participation: Audit and Do-it-yourself (DIY). The Audit path provides a no-cost energy audit conducted by a Small Business Energy Auditor. The Audit path is intended for participants who request assistance in identifying potential energy-saving measures for implementation. The DIY path does not include an energy audit and is intended for participants who have identified one or more energy-saving measures that they wish to implement. Participants have 180 days<sup>6</sup> following preapproval to complete their projects.

SBES applicants have the choice of two program applications that partially serve to determine whether their project will follow the Audit or DIY path:

- › Opportunity Worksheet: Participants who do not know which measures to implement or are interested in receiving a no-cost energy audit use the Opportunity Worksheet to apply. E1 uses the information from the Opportunity Worksheet and the business' electricity consumption history provided by NS Power to determine whether the applicant is eligible for SBES and if an audit would help identify additional potential energy-saving upgrades.
  - › Participants who are approved for a no-cost audit proceed via the Audit path.
  - › Participants who are not approved for a no-cost audit may choose to have an audit conducted at their own expense and proceed via the DIY path.
  - › Participants who are not approved for a no-cost audit and who choose not to conduct an audit at their own expense may proceed via the DIY path.
- › Before You Buy Commercial Product Rebate Application: Participants who know which measures they plan to implement and are not interested in receiving a no-cost audit complete the Before You Buy Commercial Product Rebate Application. Once approved by E1, these participants proceed via the DIY path.

Figure 1 and Figure 2 below illustrate the key steps of the participation process for the Audit and DIY paths respectively.

---

<sup>5</sup> The maximum consumption criterion was updated from 350,000 kWh to 600,000 kWh in 2024

<sup>6</sup> The maximum period allowed for project completion was updated from 120 days to 180 days in 2024.

**Figure 1: 2024 Audit Path Participation Process**

**Figure 2: 2024 DIY Path Participation Process**

Rebates vary according to factors related to specific technologies, including incremental costs, adoption rates, and the strategic importance of a given technology to SBES and the E1 portfolio.

In 2021, E1 launched the Commercial Direct Install (CDI) pilot. The pilot provides small businesses with free-of-charge direct installations of energy efficient products. E1 indicated that CDI was still in the pilot stage in 2024.

SBES was aimed at achieving net electrical energy savings of 10.592 GWh and net peak demand savings of 2.558 MW at the generator in 2024.

## 1.2 Follow-up on Past Evaluation Report Recommendations

The Evaluator evaluated SBES in previous years and issued improvement recommendations. Table 5 below provides a summary of the implementation status of past recommendations that were carried forward. The Evaluator notes that all remaining recommendations are in progress.

**Table 5: Implementation Status of Past Recommendations for SBES**

| #            | Past Recommendations                                                                                                                                                                                                            | Status      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2023-SBES-R1 | Consider improvements to the Customer Information System, notably by reviewing how missing entries are treated and extracting more information from the Customer Information System to allow validating automated calculations. | In progress | In 2024, E1 staff explored methods to improve missing entries and validate automated calculations within the Customer Information System (CIS). E1 staff are investigating how to implement proposed improvements in the CIS.                                                                                                                                                                                                                        |
| 2023-SBES-R2 | Consider implementing communication strategies for participants who are approaching their project expiration date.                                                                                                              | Complete    | E1 implemented communication strategies by increasing project pre-approval expiry from 120 to 180 days and by launching a customer automated email journey. Two email reminders are sent to customers. The first email is sent 90 days after preapproval to encourage customers to complete their projects. The second email is sent 150 days after preapproval to encourage customers to reach out to E1 for assistance to complete their projects. |

## 1.3 Participation History

In 2024, SBES rebated a total of 61,673 units: 650 through the Audit path, 60,273 through the DIY path, and 750 through the CDI Pilot. Participation in SBES,<sup>7</sup> in terms of units rebated, increased by 53% compared to 2023 levels. This increase was mainly due to the DIY path that represented 98% of total units rebated and in which participation increased by 57% compared to 2023 levels. The CDI Pilot units rebated decreased by 48% in 2024 compared to 2023 levels.

<sup>7</sup> As of 2024, the SBES participation metric used was the number of rebated units. However, prior to 2024, SBES participation was reported in terms of projects completed, so this metric is also included in Figure 3 to provide historical context.

**Figure 3: Overview of SBES Participation, 2017-2024**

The increased participation is reflected in gross energy and peak demand savings, as illustrated in Figure 4 below. Gross energy and peak demand savings increased respectively by 47% and 46% in 2024 compared to 2023.

**Figure 4: Evolution of SBES Gross Savings, 2017-2024**

As presented in Figure 5 below, lighting represented a slightly larger proportion of total program energy savings in 2024 as compared with 2023, while HVAC represented a smaller share.

**Figure 5: 2023-2024 Energy Savings per Measure Category**

## 2 SBES Evaluation Approach

The 2024 SBES evaluation consisted of a condensed impact evaluation, which also covered the Commercial Direct Install (CDI) pilot. The main objectives of the 2024 SBES evaluation were as follows:

- › Calculate gross and net SBES results, namely electrical first-year and lifetime energy savings, peak demand savings, as well as avoided GHG emissions
- › Calculate spillover levels using non-participant surveys

The Evaluator identified key research questions aimed at achieving the above objectives. Table 6 outlines the evaluation objectives and maps them to the Evaluator's research questions, methods, and sample sizes (n). Each method is described further below.

**Table 6: 2024 SBES Evaluation Approach**

| Evaluation Objectives                | Research Questions                                                                                                                                                                                                                                                                                                      | Methodology                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Tracking Sheet Audit

Prior to performing the savings calculation review, the Evaluator performed an audit of the final 2024 tracking sheet to ensure it was complete and the entered data were consistent. The detailed protocol used for the tracking sheet audit and the results obtained are presented in Appendix III.

<sup>8</sup> The 2024-2025 DSM MA is a reference document that provides an in-depth review of all parameters necessary to calculate the annual and lifetime gross energy and peak demand savings of most prescriptive measures and some semi-prescriptive measures offered through E1's DSM program portfolio. In addition, the Measure Assessment includes effective useful life values for all measures offered in E1's program portfolio. For the evaluations conducted during the last two years of the 2023-2025 DSM cycle, the Evaluator refers to the values presented in the 2024-2025 DSM MA.

## Unitary Savings Review

As part of the 2024-2025 DSM MA activities, and based on the results of both a literature review and a tracking sheet data review, the Evaluator reviewed the equations, parameters, and assumptions used to establish savings values for ten SBES. The 2024-2025 DSM MA was then updated accordingly.

## Calculations Using Evaluation Results

Building on all the above methods and collected data, the Evaluator calculated the first-year and lifetime gross energy and peak demand savings as per the calculation methodology presented in Section 4.2.

## Non-participant Survey

Narrative Research completed telephone surveys<sup>9</sup> with a sample of 30 SBES non-participants to identify any non-participant spillover that should be attributed to SBES and to collect non-participant perspectives. The sample of non-participants consisted of 30 businesses randomly selected among the pool of Nova Scotia businesses satisfying the following criteria:

- › Business customers with an annual electricity consumption under 600,000 kWh; and
- › Businesses that have never participated in either SBES or Business Energy Rebates (BER).

The average length of the telephone interviews was nine minutes and 55 seconds. Surveys were conducted between November 1 and 11, 2024. Drawing a random sample of 30 participants from a population of 1,200 yields a margin of error of 14.9% at a 90% confidence level, which applies to results for non-participant perspectives (a distinct margin of error is established for spillover results).

The non-participant survey questionnaire, profile of non-participants, and data tables for all responses received are included in Appendix I.

## GHG Emission Reduction Calculation

To obtain net avoided GHG emissions in CO<sub>2</sub> eq for SBES, the Evaluator multiplied the net energy savings by the latest Nova Scotia-specific factor for GHG emissions generated by electricity production. This factor was established using Nova Scotia Power (NS Power) data.

## Note on Margins of Error

For evaluation activities that yield quantitative results based on a sample, the Evaluator aimed to achieve a maximum margin of error of 10% at a confidence level of 90%. This means that, if measurements were conducted many times with different samples, the data would be within 10 percentage points above or below the percentage reported 90% of the time. Thus, the margin of error indicates the relative level of precision<sup>10</sup> of a measurement, while its associated confidence level indicates the probability of a measurement falling within the margin of error.<sup>11</sup>

As part of the 2024 SBES evaluation, no data-collection activities warranted the calculation of margins of error. The margins of error are listed alongside free-ridership results that were obtained as part of the 2023 evaluation in the applicable sections herein. Examples of calculations used to establish margins of error are provided in Appendix II of the 2024 DSM Program Evaluation Executive Summary.

---

<sup>9</sup> Findings associated with questions where there were 20 responses or less are reported as counts and not percentages.

<sup>10</sup> Precision refers to how reproducible a set of measurements is. However, it does not consider how close the measured values are to the true values; this would refer to accuracy.

<sup>11</sup> As part of this evaluation, the confidence levels and margins of error only take random sampling errors into account; they do not reflect non-sampling errors or biases such as data entry errors, inaccurate responses from respondents, or the inability to contact certain people.

### 3 SBES Non-participant Perspectives

This section presents the results of the perspectives collected as part of the SBES non-participant survey. First, program awareness and sources are presented, followed by participation barriers and respondent energy efficiency project history.

#### 3.1 Program Awareness and Sources

When asked without prompting, close to two-thirds (63%) of non-participants said they were not aware of any rebate programs that E1 offers to small businesses for energy efficiency upgrades. Non-participants who were unaware or did not know of any E1 program offered to small businesses (n=26) were read a brief description of SBES and then asked if they had heard of the program component. Just over half (54%) said they were still unaware of the component even after hearing the description, while just under half (46%) said they were aware of the component after hearing the description. Overall, 53% of non-participants were aware of SBES, whether before the survey (unaided) or after hearing a description (aided).

**Figure 6: 2024 Non-participant SBES Awareness**

The most common sources of awareness among those who knew about SBES (whether unaided or aided) included receiving an information brochure (4), hearing about the program from a contractor (4), and receiving an email or electronic newsletter (3). Fewer non-participants became aware of SBES through social media (2), TV/radio ads (2), and the E1 website (2).

#### 3.2 Program Participation and Barriers

Among non-participants who had heard of SBES, five had applied to participate in the past, while 11 had not. Among those who had participated in SBES, three completed their participation and received their rebates, while the remaining two did not.

Among non-participants who either did not apply to participate or did not complete the participation process (n=13), a variety of reasons is cited for not doing so. Already upgraded lighting or lighting that was installed before SBES was launched, lack of awareness about the existence of the program component, and lack of interest in making upgrades to a leased space were most commonly cited.

### 3.3 Past Energy Efficiency Projects Among Small Businesses

#### 3.3.1 Energy Efficiency Project – History

Non-participants are almost equally divided into those who had implemented energy efficiency projects without financial assistance from E1 (47%)<sup>12</sup> and those who had not (50%). Of those who had implemented energy efficiency projects with no financial assistance from E1 (n=14), three had done so in 2024, two in 2023, and one each in 2022, 2021, and 2020. As illustrated in Figure 7 below, four non-participants had implemented energy efficiency projects with no financial assistance from E1 prior to 2020, while two did not recall when they did so.

**Figure 7: Energy Efficiency Projects Implemented Without E1 Financial Assistance**

#### 3.3.2 Energy Efficiency Project – Motivations

Among the eight non-participants who had implemented energy efficiency projects between 2020 and 2024, five said their reason for installing energy efficiency upgrades was to replace equipment that was at the end of its useful life with more efficient equipment, two said they replaced functional equipment with more efficient units (prior to the equipment reaching its end of useful life), and one indicated that they added new equipment to supplement the existing equipment.

<sup>12</sup> Within the past five years.

**Figure 8: Reasons for Installing Energy Efficiency Upgrades**

## 4 SBES Impact Evaluation

The objectives of the 2024 SBES impact evaluation were to determine gross and net electrical energy and peak demand savings.

### 4.1 Tracking Sheet Audit

To ensure program component results were reliably compiled, the Evaluator first performed a tracking sheet audit aimed at verifying the completeness and consistency of the data submitted by E1. The results obtained from the tracking sheet audit are presented in Appendix III. The tracked savings results presented in this report therefore refer to the corrected tracked savings validated by the Evaluator.

### 4.2 Gross Savings

Gross savings correspond to the change in energy consumption resulting from actions taken by participants regardless of their reasons for participating.<sup>13</sup> For each SBES Audit or DIY project, E1 calculates gross savings using the standard equations defined in the CIRx Screening Tool<sup>14</sup> or the custom calculations performed by energy auditors or E1 SBES staff. For the CDI pilot, savings are based on unitary savings algorithms.

#### 4.2.1 Unitary Energy and Peak Demand Savings

Savings for SBES Audit and DIY projects are established through calculations using data specific to each project. The 2024-2025 DSM MA provides a detailed description of inputs, references, and unitary savings calculations for all measure categories. As part of the unitary savings review performed in 2024, the Evaluator validated these parameters for the top 10 SBES measures. Below is a summary of the changes made to the unitary savings inputs or calculations for SBES measures. All other parameters remained unchanged.

- › For air-source heat pumps less than 65,000 Btu/h (excluding air-to-water), the baseline seasonal energy efficiency ratio (SEER) value was changed from 13 to 14.
- › For efficient refrigeration compressors, the algorithm was simplified, and the low-temperature full-load hours parameter was changed from 5,858 to 4,139 hours.
- › For brushless direct current (DC) motors, the baseline output power was changed from 132 to 42 watts and a load factor of 90% was introduced.
- › For dairy scroll compressors, the baseline energy efficiency ratio (EER) value as well as the milk weight and change in milk temperature parameters were updated.
- › For LED lamps (CDI only), the peak coincidence factor (PCF) was changed from 59% to 54%.

---

<sup>13</sup> Definition adapted from: National Renewable Energy Laboratory, The Uniform Methods Project Chapter 23: Estimating Net Savings: Common Practices, September 2014, p. 3. [http://energy.gov/sites/prod/files/2015/02/f19/UMPChapter23-estimating-net-savings\\_0.pdf](http://energy.gov/sites/prod/files/2015/02/f19/UMPChapter23-estimating-net-savings_0.pdf) (last accessed November 25, 2016).

<sup>14</sup>The CIRx Screening Tool is a tool provided by E1 and that presents the savings calculation methodologies, assumptions, and calculation parameters for measures implemented under SBES.

## 4.2.2 Installation Rates

Installation rates are accounted for in the adjustment ratios for SBES Audit and DIY projects, as documented in the 2024-2025 DSM MA update.

The CDI pilot adjustment ratios do not encompass installation rates. For the pilot, the Evaluator assumed an installation rate of 100% since no activities aimed at establishing installation rates were conducted during the 2024 evaluation.

## 4.2.3 Interactive Effects

Interactive effects occur when the implementation of energy efficiency measures has an impact on the energy consumption of other elements such as heating and cooling. For the SBES Audit and DIY paths, these are taken into account through the gross savings standard equation in the E1 CIRx Screening Tool. Since 2016, building-specific interactive effects factors have been used for both energy and peak demand savings. As part of the 2023 SBES evaluation, the Evaluator ensured that E1 used the correct interactive effects factors for reviewed projects based on site visit observations. Where applicable, the Evaluator adjusted the interactive effects factor based on the CIRx Screening Tool value that most accurately corresponded to the situation observed on site. The interactive effects adjustments are included in the adjustment ratios established in 2023,<sup>15</sup> and this assumption remains valid in 2024.

For the CDI pilot, the Evaluator established average interactive effects factors to be applied to each measure in the 2024-2025 DSM MA; these have not been changed since 2022.

## 4.2.4 Effective Useful Life

As part of the 2024-2025 DSM MA activities, the Evaluator reviewed the EUL values used in the calculation of electrical energy savings that are expected to persist over time. The EUL values established in previous evaluations remained valid for the 2024 evaluation with the exception of the EUL values for air-source heat pumps, photovoltaic systems, and lighting measures for which the baseline changes over the life of the measures. These EUL values were revised as part of the 2024-2025 DSM MA update. The gross weighted average EUL value is equal to 16.4 years.

**Table 7: 2024 SBES Equivalent EUL and Gross Lifetime Unitary Savings Values**

| Product                                                               | Tracked Equivalent EUL [years] | Evaluated Equivalent EUL [years] | Evaluated Gross Lifetime Unitary Savings [kWh] |
|-----------------------------------------------------------------------|--------------------------------|----------------------------------|------------------------------------------------|
| LED Lamps                                                             | 2.0                            | 1.0                              | 211                                            |
| LED Nightlights                                                       | 22.8                           | 1.0                              | 29.3                                           |
| Air-source Heat Pumps Less Than 65,000 Btu/h (excluding air-to-water) | 18.0                           | 18.0                             | 406,871                                        |
| Air-source Heat Pumps Greater Than or Equal to 65,000 Btu/hr          | 15.0                           | 20.0                             | 871,651                                        |
| Photovoltaic Systems                                                  | 22.4                           | 30.0                             | 281,697                                        |

<sup>15</sup> The adjustment ratios for each path and each measure category are documented in the 2024-2025 DSM MA.

## 4.2.5 Evaluated Gross Savings

To obtain evaluated gross savings, the Evaluator applied the adjustment ratios<sup>16</sup> established as part of the 2023 SBES impact evaluation to 2024 tracked savings. Table 8, Table 9, and Table 10 below present the evaluated total gross savings at the meter and at the generator for both SBES paths and the CDI pilot respectively. The savings at the generator were calculated by applying the appropriate line loss factor for each participant based on their rate code. The line loss factors correspond to the values submitted to the Nova Scotia Utility and Review Board (NSUARB) as part of the 2014 Cost of Service Study Progress Update.<sup>17</sup>

---

<sup>16</sup> The adjustment ratios for each path and each measure category are documented in the 2024-2025 DSM MA.

<sup>17</sup> Nova Scotia Utility and Review Board, Matter M06555, 2014 Cost of Service Study Progress Update, Exhibit N-2.09, Appendix I1. For municipal utility participants, the line loss factor of the most similar NS Power rate code was assumed.

Figure 9 and Figure 10 below compare tracked gross savings to evaluated gross savings for electrical energy and peak demand savings respectively. Evaluated gross electrical energy savings and peak demand savings were approximately 4% and 6% above tracked values respectively, primarily due to corrected adjustment ratios and line loss factors

**Figure 9: 2024 SBES Tracked and Evaluated Gross Energy Savings at the Generator**

**Figure 10: 2024 SBES Tracked and Evaluated Gross Peak Demand Savings at the Generator**

As presented in Table 12 below, GHG emission reductions were calculated by applying the Nova Scotia-specific factor<sup>18</sup> for GHG emissions generated by electricity production to SBES gross savings.

<sup>18</sup> At the time of writing, 2024 data were not yet available. The Nova Scotia-specific factor was obtained from Nova Scotia Power's 2023 total system emissions data (4,931,152 CO<sub>2</sub> eq tonnes), and total electricity generation (10,442 GWh) was drawn from the following two sources: Nova Scotia Power, Total System Emissions, <https://www.nspower.ca/clean-energy/air-emissions-reporting> (last accessed September 27, 2024) and Emera Inc., Emera Inc. 2023 Annual Report, p. 31, available at [https://s25.q4cdn.com/978989322/files/doc\\_financials/2023/ar/Emera\\_2023\\_AR\\_FINAL.pdf](https://s25.q4cdn.com/978989322/files/doc_financials/2023/ar/Emera_2023_AR_FINAL.pdf) (last accessed September 27, 2024).

## 4.3 Net Savings

The Evaluator determined the net energy and peak demand savings, i.e. the electrical energy and peak demand savings that can be reliably attributed to the program component, by estimating the NTGR. More precisely, the Evaluator established the NTGR by accounting for free-ridership and spillover effects that positively or negatively affect the energy savings generated by the program component.

### 4.3.1 Free-Ridership

For SBES, free-ridership occurs when participants would have implemented energy efficiency upgrades in the absence of the program component. The free-ridership levels for DIY and Audit projects were assessed during the 2023 evaluation using a self-report approach that involved asking participants a set of questions during a telephone survey. Since no data collection aimed at updating the free-ridership levels was conducted in 2024, the Evaluator used the 2023 free-ridership levels. For the CDI pilot, no activity was conducted to establish a free-ridership level in 2023; thus, the Evaluator assumed no free-ridership.

Table 13 outlines the free-ridership level used for the 2024 SBES evaluation.

**Table 13: 2024 SBES Free-ridership Levels**

| Project Path                  | Average Free-ridership Level | Margin of Error |
|-------------------------------|------------------------------|-----------------|
| DIY (based on 2023 results)   | 20%                          | 5.2%            |
| Audit (based on 2019 results) | 12%                          | 6.5%            |
| CDI Pilot                     | -                            | N/A             |

### 4.3.2 Participant Spillover

For SBES, spillover occurs when participants implement eligible energy efficiency measures due to the influence of having previously participated in the program component without receiving any kind of additional support. As there was no data collection to update participant spillover levels in 2024, the Evaluator used the 2023 spillover levels, which were found to be nil.

### 4.3.3 Non-Participant Spillover

Using the approach described in Section 2, the Evaluator assessed non-participant spillover from a sample of 30 commercial customers. Respondents were asked if they had implemented energy efficiency projects or installed more efficient equipment in the last five years without receiving financial assistance from E1, and whether E1 had some influence on their decision to implement the measures. Respondents were asked about several influencing factors, including previous participation in other E1 programs, information or communications published by E1, and information provided by E1 representatives or members of the “Efficiency Nova Scotia Preferred Partner Network”. Respondents who had implemented energy efficiency measures were asked to estimate electric energy savings associated with these measures, either in terms of annual electricity bill savings or in annual electric energy savings (in kWh or % of annual consumption). The non-participant survey questionnaire, profile of non-participants, and data tables for all responses received are included in Appendix I and II.

Of the 30 respondents, 14 indicated that they had implemented energy efficiency measures without receiving financial assistance from E1. Six of those 14 respondents either indicated that they had implemented the measures before 2020 or that they did not know when measures were implemented and were therefore not asked the remainder of the survey questions. Of the eight respondents who said they implemented measures in 2020 or later, five implemented lighting measures, two installed heat pumps and one installed more efficient electronic equipment. Also, of those eight respondents, six responded “not at all influential” when asked whether the factors related to E1’s actions had influenced their decision to implement energy efficiency measures, while one responded “not very influential” and one responded “somewhat influential”. The measure implemented by that last respondent was the installation of six LED luminaires, which equates to negligible savings.

As a result of the non-participant survey findings, the Evaluator found the non-participant spillover level to be nil.

### 4.3.4 Net-to-gross Ratio Calculation

The NTGR results from the comprehensive impact evaluation performed in 2023 were used for the 2024 evaluation.

The NTGR for SBES was calculated using the following equation.

$$NTGR = (1 - \% \text{ Free-ridership} + \% \text{ Participant Spillover})$$

The NTGR results from the comprehensive impact evaluation performed in 2023, shown in Table 14 below, were used for the 2024 evaluation.

**Table 14: 2024 SBES NTGRs**

| Project Path | Free-ridership | Participant Spillover | NTGR |
|--------------|----------------|-----------------------|------|
| DIY          | 20%            | 0%                    | 0.80 |
| Audit        | 12%            | 0%                    | 0.88 |
| CDI Pilot    | -              | -                     | 1.00 |

### 4.3.5 Evaluated Net Savings

Net savings are defined as the energy use reductions that are specifically attributable to SBES. Program component net impacts were estimated by applying the above NTGRs to the revised gross savings by using the following equation:

$$\text{Net Savings} = \text{Revised Gross Savings} \times \text{NTGR}$$

This equation was used to calculate both electrical energy savings and peak demand savings.

The detailed results are listed in Table 15. The net energy savings resulted in 5,125 tonnes of CO<sub>2</sub> eq in net annual GHG emission reductions.

**Table 15: Evaluated 2024 SBES Net Energy and Peak Demand Savings**

| Measure Category                                            | Audit        | DIY            | CDI Pilot    | Total          |
|-------------------------------------------------------------|--------------|----------------|--------------|----------------|
| <b>Energy Savings</b>                                       |              |                |              |                |

As outlined in Figure 11 below, SBES surpassed its target of 10.592 GWh in net electrical energy savings by 2% and fell short of its target of 2.558 MW in net peak demand savings by 16%.

**Figure 11: 2024 SBES Targets and Evaluated Results**

## 4.4 Realization Rate

Table 16 below compares the tracked energy and peak demand savings values established through this evaluation to those calculated in the 2024 tracking sheet. It also includes the realization rate, representing the ratio of evaluated net savings to tracked net savings, for both energy savings and peak demand savings.

**Table 16: Comparison of 2024 SBES Tracked and Evaluated Savings at the Generator<sup>19</sup>**

|                                                                                                                     | Gross Savings |      | NTGR* | Net Savings |      | Realization Rate |
|---------------------------------------------------------------------------------------------------------------------|---------------|------|-------|-------------|------|------------------|
|                                                                                                                     | Value         | Unit |       | Value       | Unit |                  |
| Energy Savings                                                                                                      |               |      |       |             |      |                  |
| Tracked Savings by E1                                                                                               | 12.936        | GWh  | 0.81  | 10.426      | GWh  | 104%             |
| Evaluation Results                                                                                                  | 13.459        | GWh  | 0.81  | 10.854      | GWh  |                  |
| Peak Demand Savings                                                                                                 |               |      |       |             |      |                  |
| Tracked Savings by E1                                                                                               | 2.521         | MW   | 0.81  | 2.033       | MW   | 106%             |
| Evaluation Results                                                                                                  | 2.679         | MW   | 0.80  | 2.155       | MW   |                  |
| * The average NTGR values presented in this table correspond to the ratios of net savings to gross savings for SBES |               |      |       |             |      |                  |

The evaluated net electrical energy and peak demand savings were respectively 4% and 6% higher than the values tracked by E1. The differences are mainly due to corrected adjustment ratios and line loss factors.

<sup>19</sup> The results presented in Table 17 include savings for SBES and the CDI pilot.

## 5 SBES Key Findings and Recommendations

The main objectives of the 2024 SBES evaluation were as follows:

- › Calculate gross and net SBES results, namely electrical first-year and lifetime energy savings, peak demand savings, as well as avoided GHG emissions
- › Calculate spillover levels using non-participant surveys

This section provides the Evaluator's key findings and recommendations in relation to the above objectives.

**2024 SBES-Finding: SBES met its net electrical energy savings target, but did not meet its net electrical peak demand savings target.**

In 2024, SBES achieved 10.854 GWh in net electrical energy savings, thus surpassing its target by 2%. SBES achieved 2.155 MW in net peak demand savings, thus falling short of its target by 16%.

**2024 SBES-Finding: The evaluated net electrical energy savings and peak demand savings determined by the Evaluator were higher than the net savings tracked by E1.**

Energy and peak demand savings were calculated using the parameters E1 provided. Some parameters were updated based on the 2024-2025 DSM MA. Also, some other parameters like EUL, line loss factor and adjustment ratios were updated, which resulted in different energy savings. Thus, the evaluated net electrical energy savings was 4% higher than the one tracked by E1. Similarly, the net peak demand savings was 6% higher than the value tracked by E1.

**2024 SBES-Finding: Participation in SBES increased in 2024 compared to 2023 levels.**

A total of 61,673 units were rebated through SBES in 2024, including 650 units through the Audit Path, 60,273 units through the DIY Path, and 750 units through the CDI Pilot. Overall, units rebated through SBES in 2024 increased by 53% compared to 2023. The DIY Path continued to be the most popular, representing 98% of all units rebated. The CDI Pilot units rebated decreased by 48% in 2024 compared to 2023 levels.

**2024 SBES-Finding: Based on results of a survey conducted on 30 businesses, non-participant spillover was found to be nil.**

Eight survey respondents indicated that they had implemented energy efficiency measures in the last five years without receiving financial assistance from E1, but only one indicated that E1's actions were at least "somewhat influential" in their decision to implement measures, and that respondent generated negligible savings.

## CONCLUSION

Table 17 below summarizes the participation level, net-to-gross ratios (NTGRs), evaluated gross and net savings at the generator, annual GHG emission reductions, as well effective useful life (EUL) values for Direct Installation.

**Table 17: Overall 2024 Direct Installation Participation and Evaluated Savings<sup>20</sup>**

## Introduction & Screener

Hello, my name is \_\_\_\_\_ and I am calling from Narrative Research, a Halifax-based survey research company. We are performing an evaluation of energy efficiency services and programs provided by Efficiency Nova Scotia. We are interested in gathering general feedback on energy efficiency practices in small businesses in Nova Scotia. We would appreciate your help in answering questions related to your business and energy efficiency in Nova Scotia. The information you provide will be used to help Efficiency Nova Scotia improving its energy efficiency programming offered to small businesses in the province. Is this a good time for you?

**[IF NEEDED:** The survey will take about 10 minutes.]

- a. Yes
- b. No

**[IF NO, ASK “CAN WE SCHEDULE A MORE CONVENIENT TIME FOR YOU TO CONDUCT THIS SURVEY?” & RESCHEDULE.]**

Can you confirm, are you the owner or primary decision-maker **[“at a small business operating in Nova Scotia” OR PIPE IN “of <BUSINESS NAME>” (if in contacts database)]?**

- a. Yes
- b. No
- 99. (Refused) **[THANK & TERMINATE]**

**[IF NO, ASK “CAN YOU SHARE THE CONTACT INFORMATION FOR THE OWNER OR PRIMARY DECISION MAKER?” & RECORD CONTACT INFO.]**

Please indicate your business’ annual electrical energy consumption. Please choose from the from the following options: **[READ OPTIONS]**

- a. Less than 350,000 kWh annually, that is approximately \$3600/month
- b. BETWEEN 350,000 kWh annually (Approx. \$3600/month) and 600,000 kWh annually (Approx. \$6000/month)
- c. Over 600,000kWh (that is, approximately \$6000/month OR LESS in electricity bill costs) ...?
- 99. (Refused)

**[IF C/99 – THANK & TERMINATE]**

## A. Awareness, Participation & Barriers

[NOTE FOR INTERVIEWER: THERE IS A PROGRAM SIMILAR TO THE SMALL BUSINESS PROGRAM WE ARE COLLECTING FEEDBACK ON THROUGH THIS QUESTIONNAIRE. WHILE WE WILL BE FOCUSING ON SBES, “SMALL BUSINESS ENERGY SOLUTIONS” – THERE IS ANOTHER PROGRAM CALLED BER, “BUSINESS ENERGY REBATES” OFFERED BY EFFICIENCY NOVA SCOTIA THAT RESPONDENTS MAY REFER TO. THIS PROGRAM OFFERS MAIL-IN OR IN-STORE REBATES ON EFFICIENT PRODUCTS FOR ALL BUSINESS TYPES (AND SIZES). PRE-APPROVAL OF THE PRODUCT UPGRADES ARE NOT REQUIRED AS THEY ARE IN SBES. REBATE AMOUNTS VARY BY EFFICIENT PRODUCT BUT DO NOT TYPICALLY COVER UP TO 80% OF PROJECT COSTS AS IS THE CASE WITH SBES.]

- A1. [UNAIDED – DO NOT READ DESCRIPTION] Are you aware of any rebate programs that Efficiency Nova Scotia offers to small businesses for energy efficiency related equipment upgrades? If yes, please describe.

|           |                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |     |    |            |
|-----------|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|----|------------|
| a) SBES   | Small Business Energy Solutions | The program offers eligible small businesses in Nova Scotia access to energy assessments, energy efficiency contractors, rebates and financing for the installation of energy efficient upgrades. [Retrofits only.] Rebates are available in the following categories: agriculture, compressed air, space and water heating, kitchen equipment, laundry appliances, lighting, pumps (pools and general), refrigeration, variable frequency drives. | Yes | No | Don't Know |
| b) Other? |                                 | RECORD NAME & DESCRIPTION [TEXT BOX]                                                                                                                                                                                                                                                                                                                                                                                                               |     |    |            |

- A2. [ASK ONLY IF NO/DON'T KNOW/OTHER IN A1] [AIDED] I am going to read you a brief description of a rebate program offered by Efficiency Nova Scotia to small businesses in the province. Please indicate if you've heard of this program after hearing the description.

|         |                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |     |    |            |

**A3. [ASK ONLY IF A1 or A2 = YES]** How did you learn about Efficiency Nova Scotia's Small Business Energy Solutions Program? **[DO NOT READ. MULTIPLE RESPONSE.]**

- a. From a contractor
- b. From an equipment vendor
- c. From an energy auditor, recommissioning provider or energy consultant
- d. From an Efficiency Nova Scotia account representative
- e. At an event/trade show
- f. Received an email or electronic newsletter
- g. Received an informational brochure
- h. From Efficiency Nova Scotia's website
- i. From a neighbouring small business
- j. TV/radio ad
- k. Friends or colleagues
- l. Through experience with the program
- m. Through participation in another Efficiency Nova Scotia energy efficiency program for businesses (SPECIFY THE PROGRAM: \_\_\_\_\_)
- n. Through participation in another Efficiency Nova Scotia energy efficiency program for homes (SPECIFY THE PROGRAM: \_\_\_\_\_)
- 96. Other, please specify: **[OPEN-ENDED RESPONSE]**
- 98. (Don't know)

**A4. [ASK ONLY IF A1 or A2 = YES]** Have you applied to participate in the Small Business Energy Solutions Program in the past? **[DO NOT READ. ACCEPT ONE RESPONSE]**

- a. Yes
- b. No
- 98. (Don't know)
- 99. (Refused)

**A5. [ASK ONLY IF A4 = YES]** Did you complete your participation in the Small Business Energy Solutions and receive your rebate(s)? **[DO NOT READ. ACCEPT ONE RESPONSE]**

- a. Yes
- b. No
- 98. (Don't Know)
- 99. (Refused)

**A6. [ASK ONLY IF A4 = NO OR A5 = NO] What was the main reason why your business did not [IF A4 = NO “apply to participate” OR IF A5 = NO “complete your participation”] in the Small Business Energy Solutions program? [DO NOT READ AT FIRST. ACCEPT ONE RESPONSE. PROMPT BY READING LIST IF NECESSARY. RANDOMIZE.]**

- a. The time to recoup the investment/payback period / the time it takes to re-coup the equipment investment via energy savings on bills
- b. Financial challenges, even after rebate, such as lack of funds
- c. The offer of 0% on-bill financing through Nova Scotia Power was not attractive for my business
- d. I was unable to proceed as I was not eligible for the 0% on-bill financing through Nova Scotia Power
- e. The potential wait-time to receive the rebate
- f. The potential wait-time to receive pre-approval for an upgrade project
- g. Time constraints or competing priorities for your business
- h. Concern that rebates will not be available when project is completed
- i. Concern that energy efficiency upgrades won't work as well as advertised
- j. Need for information or technical support to get a project idea off the ground
- k. Availability of qualified contractors to complete upgrade or renovation projects
- l. Availability of the desired upgrade equipment to install for your business
- m. Do not know which energy efficiency upgrades to prioritize for my business
- n. Reducing energy costs is not a priority for my business at this time
- o. Unsure about which energy efficiency upgrades my business can complete versus which are the landlord's responsibility
- p. Cannot obtain permission from my landlord to complete upgrades
- q. Not interested in making upgrades in a leased space
- 96. Other, please specify: **[OPEN-ENDED RESPONSE]**
- 98. (Don't know)
- 99. (Refused)

## **B. Non-Participant Spillover**

**B1.** Have you implemented energy efficiency projects or installed more efficient equipment aimed at generating electricity savings in your establishment in the last five years without receiving financial assistance from Efficiency Nova Scotia?

- a. Yes
- b. No **[SKIP TO FIRMOGRAPHICS]**
- 98. Don't know **[SKIP TO FIRMOGRAPHICS]**

**B2.**     **[IF B1 = YES]** In which year?

- a.     2024
- b.     2023
- c.     2022
- d.     2021
- e.     2020
- f.     2019 or before **[SKIP TO FIRMOGRAPHICS]**
- 98.    Don't know **[SKIP TO FIRMOGRAPHICS]**

**B3. Which energy efficiency upgrades did you install? [PUT CODES IN ALPHABETICAL ORDER. DO NOT READ. MULTIPLE RESPONSES]**

- a. Lighting
- b. Thermal envelope: Insulation (wall, floor, or roof)
- c. Thermal envelope: Doors/windows
- d. Heating system (in general)
- e. Geothermal
- f. Radiant floor
- g. Heat recovery ventilation (HRV) system
- h. Air-conditioning system
- i. Domestic hot water heating system
- j. Solar water heater
- k. Solar space heating system
- l. Efficiency refrigeration system
- m. Efficient compressor/compressed air system
- n. Heat recovery system
- o. Variable frequency drive (VFD)
- p. Electronic control HVAC system
- q. Efficient motor
- r. Efficient fans
- s. Efficient pump
- t. Efficient pool pump
- u. Kitchen equipment/appliances
- v. Mechanical system
- w. Piping/aqueduct
- x. Heat pump
- y. Laundry appliances
- z. Agricultural equipment
- aa. IT/server equipment
- 96. (Other, please specify \_\_\_\_\_)
- 98. (Don't know) **[SKIP TO FIRMOGRAPHICS]**

**B4. [IF B3 = A) Lighting]** What type of lighting did you install? Please indicate how many of each category. **[READ AS NEEDED, MULTIPLE RESPONSES – COLLECT QUANTITY IN NUMERIC BOX]**

- a. Interior lighting – T5/T8 fluorescents
- b. Interior lighting – LED luminaires
- c. Interior lighting – LED exit signs
- d. Interior lighting – Occupancy sensor
- e. Various interior lighting
- f. Exterior lighting – Photovoltaic cell
- g. Exterior lighting – LED luminaires
- h. Exterior lighting – High-pressure sodium (HPS) lamps
- i. Various exterior lighting
- 96. (Other, please specify \_\_\_\_\_)
- 98. (Don't know)

**B5. [IF B3 = NOT A) Lighting]** Please describe the upgrade that you implemented **[PROBE FOR: type/size/model/efficiency level/quantity of equipment/appliance OR quantity/size/area/type (R-value) of insulation]** **[INSERT TEXT BOX with DON'T KNOW option.]**

**B6.** When you installed the energy efficiency upgrades you mentioned just now, what was the estimated electricity energy savings associated with the project(s) you completed? Please frame your answer around annual savings. **[NOT REQUIRED. HELPFUL IF THEY CAN RESPOND.]**

This estimation can be in dollars, kWh, or percentage of electricity consumption.

Write the amount in dollars per year: \$ \_\_\_\_\_

Write the savings in kWh per year: \_\_\_\_\_

Write the % of annual electricity consumption: \_\_\_\_\_%

98. (Don't Know)

**B7.** Which of the following situations best describes why you installed the energy efficiency upgrades you outlined just now? **[ACCEPT ONLY ONE ANSWER. ONLY READ IF NECESSARY.]**

- a. Early replacement of functional equipment (in other words, prior to the end of useful life) with more efficient units
- b. Replacement of equipment at the end of useful life with more efficient units
- c. Urgent or mandatory replacements of equipment
- d. Adding equipment to improve the efficiency of existing units (for example controls)
- 96. (Other, please specify: \_\_\_\_\_)
- 98. (Don't know)

**B8.** Did you receive some form of financial assistance for these energy efficiency upgrades to your business?

- a. Yes
- b. No
- 98. (Don't Know)

**B9.** [IF B8 = Y] Who provided the financial assistance? [DO NOT READ – MULTIPLE RESPONSES POSSIBLE]

- a. Government of Canada
- b. Natural Resources Canada/Canada Greener Homes Program
- c. The Government of Nova Scotia
- 96. (Other, please specify: \_\_\_\_\_)
- 98. (Don't know)

**B10.** Thinking about when you decided to install energy efficiency upgrades in your business, please indicate how influential the following factors were using a response of **very, somewhat, not very or not at all...** [READ, ROTATE]

- a. Information you received from Efficiency Nova Scotia programs targeting business clients... in your decision?
- b. Information you read on the Efficiency Nova Scotia website... in your decision?
- c. Information you received through Efficiency Nova Scotia communications, promotional materials or publicity... in your decision?
- d. Past participation in a different energy efficiency program offered by Efficiency Nova Scotia (not for small businesses) ... in your decision?
- e. Information and advice from an Efficiency Nova Scotia representative... in your decision?
- f. Recommendations from a member of the Efficiency Nova Scotia Preferred Partner Network (supplier, contractor, etc.) ... in your decision?

[READ CHOICES & RECORD ONE RESPONSE OPTION BELOW FOR A-F]

- 1. Very influential
- 2. Somewhat influential
- 3. Not very influential
- 4. Not at all influential
- 98. (Don't know) [DO NOT READ]

## C. Firmographics

These final questions are asked for statistical purposes only. Results will be reported in aggregate and your responses will remain confidential.

**C1.** What is the main source of energy used for space heating in your establishment/main location?

- a. Electricity
- b. Natural gas
- c. Oil
- d. Propane
- 96. (Other, please specify \_\_\_\_\_)
- 98. (Don't know)

**C2.** And what is the main source of energy used to heat water?

- a. Electricity
- b. Natural gas
- c. Oil
- d. Propane
- 96. (Other, please specify \_\_\_\_\_)
- 98. (Don't know)

**C3. What is the main activity of your business? [DO NOT READ—BUT CONFIRM WITH RESPONDENT THAT THE CATEGORY YOU CHOOSE IS CORRECT]**

- a. Educational services
- b. Food sales (i.e. grocery, health food store, bulk food store, greengrocer, etc.)
- c. Food service (restaurant, bar, café, etc.)
- d. Health care
- e. Dental care
- f. Veterinary
- g. Lodging
- h. Retail
- i. Office
- j. Public assembly
- k. Public order and safety
- l. Religious worship
- m. Service
- n. Warehouse and storage
- o. Construction
- p. Manufacturing
- q. Social assistance
- r. Farming
- s. Property management
- 96. (Other: please explain \_\_\_\_\_)
- 98. (Don't know)
- 99. (Refused)

**C4.** Approximately how many full-time equivalent workers are employed with your company (at all locations as a total)? **[DO NOT READ, CODE APPROPRIATE CATEGORY] [IF ASKED: FULL-TIME EQUIVALENT WORKERS REFERS TO THOSE WORKING 35 HOURS OR MORE PER WEEK.]**

- a. Fewer than 5
- b. 5 to 9
- c. 10 to 19
- d. 20 or more
- 98. (Don't know)
- 99. (Refused)

**C5.** Do you own or rent your business location(s)?

- a. Own
- b. Rent
- c. Multiple locations – mix of ownership and renting
- 96. (Other: please explain \_\_\_\_\_)
- 98. (Don't know)
- 99. (Refused)

**C6.** How many locations does your business have in Nova Scotia? **[RECORD A NUMBER 1-99; 998 = DON'T KNOW, 999 = REFUSED]**

**[END: Those are all the questions I have for you. I thank you very much for your time and cooperation and have a nice day!]**

## APPENDIX II

### SBES Non-Participant Survey Results

The participant survey results are presented in the following tables. Please note that Business Activities are noted as such in the following tables: **Lodging = L, Retail = R, Service = S, Warehouse = W, Manufacturing = M, Auto/Car Repairs/Dealership = A, Other = O.**

**TABLE A1: [UNAIDED]**

|                        | OVERALL<br>% | FULL-TIME<br>WORKERS |           |          | OWN OR<br>RENT |           | BUSINESS' MAIN ACTIVITY |          |          |          |          |          |           |

## APPENDIX III

### SBES 2024 Tracking Sheet Audit

This appendix presents the main results of the tracking sheet audit performed by the Evaluator, which was aimed at:

- › Verifying that all data fields required for the evaluation were included and properly filled out in the tracking sheet submitted by EfficiencyOne (E1)
- › Ensuring that tracked results were accurate by:
  - › Verifying that parameters used to calculate program results (gross and net energy and peak demand savings at the generator) were consistent with previous evaluation results
  - › Validating that all calculation steps were performed consistently.

Table 1 presents the corrected tracked savings resulting from all changes made by the Evaluator.

**Table 1: 2024 SBES Corrected Tracked Savings**

| Program Component Results                    | Value Tracked by E1 |      | Corrected Tracked Value |      | Relative Difference |
|----------------------------------------------|---------------------|------|-------------------------|------|---------------------|
|                                              | Value               | Unit | Value                   | Unit | Value               |
| <b>SBES – Audit &amp; DIY</b>                |                     |      |                         |      |                     |
| Gross Energy Savings – at the Generator      | 12.790              | GWh  | 12.791                  | GWh  | 0.01%               |

| Net Energy Savings – at the Generator        | 10.280              | GWh  | 10.281                  | GWh  | 0.01%               |
| Net Peak Demand Savings – at the Generator   | 2.011               | MW   | 2.011                   | MW   | 0.00%               |
| <b>Commercial Direct Install (CDI) Pilot</b> |                     |      |                         |      |                     |
| Gross Energy Savings – at the Generator      | 0.162               | GWh  | 0.145                   | GWh  | -10%                |
| Gross Peak Demand Savings – at the Generator | -                   | MW   | 0.023                   | MW   | -                   |
| Net Energy Savings – at the Generator        | 0.162               | GWh  | 0.145                   | GWh  | -10%                |
| Net Peak Demand Savings – at the Generator   | -                   | MW   | 0.023                   | MW   | -                   |
| <b>Total</b>                                 |                     |      |                         |      |                     |
| Gross Energy Savings – at the Generator      | 12.952              | GWh  | 12.936                  | GWh  | -0.12%              |
| Gross Peak Demand Savings – at the Generator | 2.498               | MW   | 2.521                   | MW   | 0.92%               |
| Net Energy Savings – at the Generator        | 10.442              | GWh  | 10.426                  | GWh  | -0.15%              |
| Net Peak Demand Savings – at the Generator   | 2.011               | MW   | 2.033                   | MW   | 1.09%               |

Given that the same net-to-gross ratios and line loss factors were used, SBES corrected tracked savings are very similar to those tracked by E1. Without the energy and peak demand unitary savings, it is difficult to calculate accurate corrected tracked values.

As for the CDI pilot, the difference between corrected tracked energy savings and tracked energy savings is due to interactive effects factors and adjustment ratios not taken into account in the calculation of tracked savings. There were also some errors in the tracked energy line loss factors. No peak demand savings at the generator were tracked in the tracking sheet.

## APPENDIX IV

### SBES 2024 Recommendations

The Evaluator made no specific recommendation as part of the 2024 evaluation of SBES.

|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Accuracy</b>                           | Reflects the proximity of measurements to the true value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Adjustment ratio</b>                   | The ratio of evaluated results to tracked results. This ratio expresses the adjustment made to tracked savings or other tracked values such as effective useful life values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Available Demand Response Capacity</b> | The capacity that is available to Nova Scotia Power (NS Power) to reduce system peak demand. This capacity is calculated based on the first two hours of all events called between December and February, excluding weekends and holidays. If an event is shorter than two hours, only the first hour is used to measure available demand response (DR) capacity. Available DR capacity is evaluated on a per-participant basis based on the average demand reduction observed for each event in which the participant was scheduled to participate. E1's total available DR capacity is the sum of each participant's available DR capacity. |
| <b>Baseline</b>                           | To determine gross savings, a baseline (or base case) is established, providing detailed information about the reference (e.g. pre-existing or standard) measure or equipment chosen to be compared with the efficient measure or equipment. For the reference measure or equipment, the baseline may include such information as the hours of operation, wattage, and base consumption.                                                                                                                                                                                                                                                      |
| <b>Bias</b>                               | Systematic deviations of measurements from the true value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Billing calibration</b>                | An activity that consists of adjusting the expected energy savings based on the relative difference between the results of energy simulations and the actual energy consumption of a building or system.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Confidence interval</b>                | The estimated range of values that is likely to include unknown population parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Demand response</b>                    | Demand response measures generate savings in the form of available capacity or a load reduction in response to events called by the electric utility (NS Power) to reduce the load at strategic moments. These events can be called at any time and for any duration, although they are usually called for one to four hours during peak periods.                                                                                                                                                                                                                                                                                             |
| <b>Displaced wattage</b>                  | The displaced wattage is defined as the difference between the wattage values of the baseline equipment or product and that of the efficient equipment or product.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>EnerGuide rating</b>                   | An EnerGuide (official brand of Natural Resources Canada) rating is a standard measure of home energy performance. It is a measure of the efficiency of the building only and does not take into account occupant behaviour. It shows how energy efficient a home is through modelled home heat losses based on several factors including building envelope characteristics, heated volume, heating systems, and air leakage.                                                                                                                                                                                                                 |
| <b>Effective useful life</b>              | The period a measure is expected to be in service and provide both electrical energy and peak demand savings. This value combines equipment life and                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                                         |                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                         | measure persistence, which includes factors such as business turnover or early retirement.                                                                                                                                                                                                                                      |
| <b>Equipment life</b>                   | The number of years installed equipment will operate before it fails.                                                                                                                                                                                                                                                           |
| <b>Equivalent CO2</b>                   | A unit of measurement indicating the amount of carbon dioxide to which various kinds of emitted greenhouse gases are equivalent in terms of warming effects. In this report, gas global warming potential is estimated over a timescale of 100 years.                                                                           |
| <b>Equivalent effective useful life</b> | The number of years by which the first-year savings estimate is multiplied to obtain lifetime energy savings. This value takes into account variations in annual electrical energy savings throughout the effective useful life due to increased baselines.                                                                     |
| <b>Evaluated savings</b>                | Gross and net electrical energy or peak demand savings calculated by the Evaluator using the parameters (unitary savings values, installation rates, interactive effects, net-to-gross ratios, etc.) validated or measured during the evaluation process. Unless otherwise specified, evaluated savings are first-year savings. |
| <b>Evaluation plan</b>                  | The evaluation plan summarizes the program description, objectives, base cases, documentation, evaluation methodology, budget, and schedule.                                                                                                                                                                                    |
| <b>First-year savings</b>               | The first full year of electrical energy or peak demand savings generated by an energy efficiency measure.                                                                                                                                                                                                                      |
| <b>Free-ridership</b>                   | Percentage of gross savings attributable to participants who would have implemented the same or similar energy efficiency measures, with no change in timing, in the absence of the program.                                                                                                                                    |
| <b>Gross savings</b>                    | Change in energy consumption and/or demand that results directly from program-related actions taken by participants in an energy efficiency program regardless of why they participated.                                                                                                                                        |
| <b>Induced consumption</b>              | Energy consumption of appliances that would have been unplugged and not replaced by participants in the absence of the program.                                                                                                                                                                                                 |
| <b>Interactive effects</b>              | Effects on the energy consumption of other systems (such as heating and cooling) in a building due to the installation of an energy efficiency measure.                                                                                                                                                                         |
| <b>In-service rate</b>                  | The proportion of incentivized products installed and operating. This rate is usually applied to programs through which rebates are offered in-store and products are likely to be stored for a certain period before being installed, such as light-emitting diode (LED) lamps.                                                |
| <b>Installation rate</b>                | The proportion of incentivized products reported as installed and that remain installed and operating at the time of evaluation. This rate is usually applied to direct install or mail-in rebate programs through which measures are expected to be installed immediately at the time of participation.                        |
| <b>Lifetime energy savings</b>          | The energy savings that occur over the lifetime of an energy efficiency measure. Lifetime energy savings account for a measure's effective useful life and any increase in the baseline efficiency level (which reduces attributable annual savings) over its lifetime.                                                         |

|                                 |                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Line loss factor</b>         | The multiplier to convert savings at the customer meter to savings at the utility generator. It accounts for the electrical losses of the transmission and distribution system.                                                                                                                                                                             |
| <b>Margin of error</b>          | The amount of random sampling error.                                                                                                                                                                                                                                                                                                                        |
| <b>Market effects</b>           | The impact of a program on the market (in terms of product availability, practices, and prices) and that extends beyond changing program participant behaviours. Market effects include spillover among non-participants.                                                                                                                                   |
| <b>Net savings</b>              | Electrical energy or peak demand savings that can be reliably attributed to a program. These include effects such as free-ridership and spillover that negatively or positively affect the savings attributable to a program.                                                                                                                               |
| <b>Net-to-gross ratio</b>       | The ratio of net electrical energy savings to gross electrical energy savings.                                                                                                                                                                                                                                                                              |
| <b>Non-sampling error</b>       | Errors arising during the course of all survey activities other than sampling. Non-sampling errors tend to lead to bias in measurements and are very difficult to quantify.                                                                                                                                                                                 |
| <b>Peak coincidence factor</b>  | The percentage of measure demand savings that coincide in time with the annual peak demand of the entire electricity system.                                                                                                                                                                                                                                |
| <b>Peak demand savings</b>      | The demand savings that coincide in time with the expected annual peak demand period of the entire electricity system. For industrial participants on an interruptible rate, peak demand savings may include savings on non-firm loads, i.e. loads that may be interrupted when NS Power's 10-minute reserve is low.                                        |
| <b>Precision</b>                | The extent to which repeated measurements agree with one another.                                                                                                                                                                                                                                                                                           |
| <b>Random sampling error</b>    | An error in measurement due to the fact that measurements are taken from a subset of the population and not the entire population.                                                                                                                                                                                                                          |
| <b>Realization rate</b>         | The ratio of evaluated savings to tracked savings.                                                                                                                                                                                                                                                                                                          |
| <b>Sample size</b>              | The number of observations or replicates included in a statistical sample.                                                                                                                                                                                                                                                                                  |
| <b>Secondary market impacts</b> | Energy consumption of appliances that would have been transferred to the secondary market if said appliances had not been retired.                                                                                                                                                                                                                          |
| <b>Spillover</b>                | Savings attributable to participants who implement additional energy efficiency measure(s) introduced by a program after participating in it once and without participating in the program a second time.                                                                                                                                                   |
| <b>Tracked savings</b>          | Gross and net savings calculated based on various parameters such as number of participants or units installed or sold, unitary savings values, installation rates, interactive effects, and net-to-gross ratios. Those parameters, with the exception of the number of participants or units installed or sold, are obtained from the previous evaluation. |
| <b>Unitary savings</b>          | Electrical energy or peak demand savings established on a unitary basis. A unit can either be a product (e.g. an 8 W LED lamp), a capacity (e.g. one tonne capacity of an air-source heat pump), or a participant (e.g. one participant taking part in a behaviour-based program).                                                                          |

## EXECUTIVE SUMMARY

This report presents the 2024 demand-side management (DSM) results of the Demand Response (DR) program administered by EfficiencyOne (E1). This program is comprised of two components: Residential DR and Business, Non-profit, and Institutional (BNI) DR. Residential DR generated available DR capacity through the Eco Shift Pilot. BNI DR generated available DR capacity through the DR Aggregator pathway. Combined, these program components encourage homeowners and businesses to reduce their electric load during peak events called by Nova Scotia Power (NS Power) by providing financial incentives for the DR capacity made available for those events.

## Evaluation Approach

The 2024 evaluation was aimed at calculating program component results, namely new and total available DR capacity. Table 1 summarizes the types of evaluation conducted for each program component and the corresponding methodology.

**Table 1: Summary of Demand Response Program Evaluation**

| Program Component           | Evaluation Type |        |               | Methodology                                                                                                                                                                                                     |
|-----------------------------|-----------------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             | Process         | Market | Impact        |                                                                                                                                                                                                                 |
| Residential Demand Response |                 |        | Comprehensive | <ul style="list-style-type: none"><li>› Tracking sheet audit</li><li>› Whole-house consumption data analysis</li><li>› Measure Assessment (MA) update</li><li>› Calculations using evaluation results</li></ul> |
| BNI Demand Response         |                 |        | Comprehensive | <ul style="list-style-type: none"><li>› Tracking sheet audit</li><li>› Project reviews</li><li>› Calculations using evaluation results</li></ul>                                                                |

## Program Performance

Table 2 presents the participation levels and evaluated new and total available DR capacity for each program component and for the Demand Response program as a whole.

**Table 2: Overall 2024 Demand Response Participation and Evaluated Results**

|                       | Participation Level |              | Evaluated Results |      |
|-----------------------|---------------------|--------------|-------------------|------|
|                       | Value               | Unit         | Value             | Unit |
| <b>Residential DR</b> |                     |              |                   |      |
| New DR Capacity       | 353                 | Participants | 0.057             | MW   |

| <b>BNI DR</b>         |                     |              |                   |      |
| New DR Capacity       | 70                  | Participants | 5.669             | MW   |
| Total DR Capacity     | 76                  | Participants | 8.034             | MW   |
| <b>Total</b>          |                     |              |                   |      |
| New DR Capacity       |                     |              | 5.726             | MW   |
| Total DR Capacity     |                     |              | 8.091             | MW   |

For 2024, Demand Response was aimed at achieving 7.240 MW in total available DR capacity at the generator. The program exceeded the planned total available DR capacity even though the Residential DR program component fell short of its target. The BNI DR program component was the largest contributor to total program available DR capacity.

The following subsections present evaluation results at the program component level.

## Residential DR Findings and Recommendations

This subsection presents the key findings and recommendations from the Residential DR evaluation.

**2024 Res DR-Finding:** In 2024, Residential DR new and total available DR capacities both amounted to 0.057 MW at the generator, thus not reaching the planned total available DR capacity of 0.210 MW.

**2024 Res DR-Finding:** Mysa thermostats were the most popular devices in Residential DR, representing 83% of all registered devices. Indeed, there were 353 participants in Residential DR, with a total of 1,307 enrolled devices composed of 1,082 Mysa thermostats, 175 Sinopé thermostats, and 50 electric vehicles (EVs) or EV chargers. Since participants continued to register throughout the season, the numbers presented above represent devices enrolled by the last event of the season. However, opted out participants and connectivity issues meant that not all enrolled devices participated in each event; of the enrolled Mysa thermostats, an average of 97% participated during the events.

**2024 Res DR-Finding:** The Evaluator decided to rely on whole-house consumption data to establish a regression model for the baseline, relying on a model that considers the time of week and outdoor temperature. Whole-house data were preferred to device-level data as they allow for the inclusion of interactive effects from equipment such as other heating systems not controlled by participating smart thermostats offsetting the reduced load associated with participating thermostats. As for the time of week method, it allows to differentiate the impact of outdoor temperature at each time of the week. The resulting 168 regression models provided sufficient accuracy. The Evaluator plans to continue using the same methodology to calculate unitary savings for thermostats in future years.

**2024 Res DR-Finding:** Preheating implementation issues prevented the program component from reaching its full potential during a few events, resulting in lower DR capacity than expected. Although the service provider intended to include 30 minutes of preheating for Events 6, 7, and 8, preheating was incorrectly implemented due to an issue being investigated and occurring during the events instead of before the events, thus resulting in negative available DR capacity for the first hour of those events. Assuming that preheat implementation errors will not occur again in future years, E1 can track available DR capacity during the next heating season using a unitary available DR capacity of 57.7 W per thermostat in comparison to the unitary available DR capacity value of 39.4 W per thermostat used in this evaluation.

**2024 Res DR Recommendation 1:** Gather and analyze the Eco Shift Pilot data again in 2025 to improve the unitary available DR capacity value accuracy and ensure it is consistent over multiple years.

## BNI DR Findings and Recommendations

This subsection presents the key findings and recommendations from the BNI DR evaluation.

**2024 BNI DR-Finding:** Total available DR capacity at the generator amounted to 8.034 MW that included 5.669 MW of new DR capacity. Therefore, BNI DR exceeded its target of 7.030 MW in total available DR capacity.

**2024 BNI DR-Finding:** Participation grew over 700% from nine participants last year to 76 participants this year. The available DR capacity per participant decreased from 263 kW in 2023 to 106 kW in 2024.

**2024 BNI DR-Finding:** Overall, the BNI DR available DR capacity calculation guidelines developed by E1 were appropriate and generally followed. The Evaluator project reviews resulted in only a small difference in available DR capacity compared to the value obtained by E1 after their project reviews. This is the result of the Evaluator mostly agreeing with the changes made by E1. Nonetheless, the Evaluator identified a few gaps in the BNI DR Baseline Considerations document to properly cover all the different adjustments encountered through the project reviews.

**2024 BNI DR Recommendation 1:** Update the BNI DR Baseline Considerations document to properly address all situations encountered through the project reviews.

- › Clearly define how to identify building operating hours and when to set the available DR capacity to zero.
- › Ensure that lookback windows are moved consistently across all similar events unless they are moved due to an abnormal load.
- › Clearly state in the document that certain events may be excluded on a per-participant basis due to missing AMI metering data because of technical issues or events not being called for participants identified as morning-only or evening-only participants.

**2024 BNI DR-Finding:** The evaluation revealed that reviewing and adjusting the results for a stratified sample of projects (20 projects with the largest available DR capacity and 10 randomly selected projects among the others) allowed the Evaluator to establish reliable evaluated available DR capacity. Indeed, the Evaluator project reviews resulted in an adjustment ratio of 0.93 with margin of error below 10%. The Evaluator also noted that, in future, sampling should be made after negative values are set to zero.

**2024 BNI DR Recommendation 2:** In the next evaluation, continue to use project reviews to establish tracked and evaluated available DR capacities.

**2024 BNI DR-Finding:** The evaluated new and total available DR capacities were 1% and less than 1% lower than the values tracked by E1 respectively. The differences are due to the adjustments made through the project reviews.

## Program Tracked and Evaluated Savings

Table 3 below presents a comparison of E1 tracked available DR capacity compared to evaluated results as well as the realization rate.

**Table 3: Comparison of 2024 Tracked and Evaluated Savings at the Generator**

|                |                                                  | Available DR Capacity |      | Realization Rate |
|----------------|--------------------------------------------------|-----------------------|------|------------------|
|                |                                                  | Value                 | Unit |                  |
| Residential DR | New Available DR Capacity                        |                       |      |                  |
|                | Tracked Available DR Capacity by E1 <sup>1</sup> | -                     | MW   | -                |
|                | Evaluation Results                               | 0.057                 | MW   |                  |
|                | Total Available DR Capacity                      |                       |      |                  |
|                | Tracked Available DR Capacity by E1 <sup>1</sup> | -                     | MW   | -                |
|                | Evaluation Results                               | 0.057                 | MW   |                  |
| BNI DR         | New Available DR Capacity                        |                       |      |                  |
|                | Tracked Available DR Capacity by E1              | 5.702                 | MW   | 99%              |
|                | Evaluation Results                               | 5.669                 | MW   |                  |
|                | Total Available DR Capacity                      |                       |      |                  |
|                | Tracked Available DR Capacity by E1              | 8.067                 | MW   | 100%             |
|                | Evaluation Results                               | 8.034                 | MW   |                  |

<sup>1</sup> For Residential DR, tracked results were not fully compiled since multiple methodologies on how to establish the available DR capacity of the measures included in 2024 were being considered. The Evaluator decided on the final methodology to be used as part of the current evaluation.

# INTRODUCTION

EfficiencyOne (E1), an independent, non-profit organization, is responsible for helping Nova Scotians improve the energy efficiency of their homes and workplaces by designing, marketing, and delivering demand-side management (DSM) for Nova Scotians. E1 provides energy efficiency, demand response and carbon mitigation services through the Efficiency Nova Scotia (ENS) franchise. Regulatory oversight of its DSM activities is provided by the Nova Scotia Utility and Review Board (NSUARB). E1 receives funding for its electricity DSM activities from Nova Scotia Power (NS Power) ratepayers.

E1 has a DSM portfolio of three residential programs, three business, non-profit, and institutional (BNI) programs, and one demand response (DR) program that are marketed to Nova Scotians through the ENS franchise. Each program has one or more program components. Econoler was commissioned by E1 to evaluate E1's 2024 DSM program portfolio.

This evaluation report relates to the DR program comprised of the Residential DR and BNI DR program components. Residential DR generated available DR capacity through the Eco Shift Pilot. BNI DR generated available DR capacity through the DR Aggregator pathway.

Table 4 lists the DR program components and the types of evaluations conducted in 2024.

**Table 4: Types of Evaluations Conducted for Each Program Component, 2024**

| Program         | Program Component           | Pathway         | 2024    |        |               |
|-----------------|-----------------------------|-----------------|---------|--------|---------------|
|                 |                             |                 | Process | Market | Impact        |
| Demand Response | Residential Demand Response | Eco Shift Pilot |         |        | Comprehensive |
|                 | BNI Demand Response         | DR Aggregator   |         |        | Comprehensive |

For the DR program, the Evaluator prepared this DSM evaluation report presenting key findings as well as the savings generated through DR initiatives, which are presented in terms of new and total available DR capacities. New DR capacity differs from total available DR capacity; the former corresponds to added DR capacity compared to the previous year while the latter corresponds to the total DR capacity that was still available during the evaluated period.

Available DR capacity differs from peak demand savings reported in other DSM evaluation reports since the former considers the potential load reduction that was made available instead of the actual load reduction that coincided with the actual utility peak period. This distinction was made since E1 does not control the calling of events and thus does not control how the resources made available to NS Power are used to reduce peak demand.

Available DR capacity is evaluated based on events called from December to February excluding weekends and holidays. Events called at any time during the day (morning or evening) are included. Available DR capacity is measured over the first two hours of a DR event and is evaluated on a per-participant basis based on the average demand reduction observed for each event in which the participant took part regardless of whether events are in the morning or evening. E1's total available DR capacity is the sum of each participant's available DR capacity. In addition, reported available DR capacity corresponds to events that occurred during the winter and that ended during the evaluated year, e.g. the 2024 available DR capacity corresponds to the DR capacity made available between December 2023 and February 2024 inclusively.

# 1 Residential DR Overview

This section describes the Residential DR program component, follows up on past evaluation recommendations, and provides an overview of Residential DR participation history.

## 1.1 Residential DR Description

In 2023, E1 officially launched the Residential DR program component. Since the fall of 2020, E1 has implemented several pilot initiatives focused on reducing demand during the Nova Scotia peak period. The Eco Shift Pilot launched in the fall of 2023, which is considered a pathway in the Residential DR program component for the purpose of this evaluation. The Eco Shift Pilot is the only Residential DR pathway that was evaluated in 2024.

The Eco Shift Pilot is a residential “bring your own device” program that provides NS Power with available DR capacity through three eligible device types: 1) Smart thermostats for electrically heated homes; 2) electric vehicles (EVs) and EV chargers; and 3) behind-the-meter batteries. Virtual Peaker is the technical partner providing the software that serves to control participating devices. When NS Power calls DR events, participating devices are remotely controlled by Virtual Peaker to reduce their loads. For example, smart thermostat setpoints are reduced and EV chargers stop charging if the EV battery is above 50% of its capacity. CLEAResult is the service provider that manages the Eco Shift Pilot, notably by managing enrollment, coordinating incentive payments, and acting as a go-between for E1 and Virtual Peaker. Participants were notified at 4 p.m. the day before an event, 15 minutes before the event, and once the event ended. Participants may opt out of any event. Events can last from two to four hours and be called any time between 7 a.m. and 11 a.m. or between 5 p.m. and 9 p.m. on non-holiday weekdays, and events cannot be called more than once per day. As presented in Table 5, NS Power called 10 events during the 2023-2024 winter peak season.

**Table 5: Eco Shift Pilot 2023-2024 Event Summary**

| Event # | Date       | Start Time | Duration (Hours) | Outdoor Temperature at Event Start (°C) |
|---------|------------|------------|------------------|-----------------------------------------|
| 1       | 01-09-2024 | 6 p.m.     | 2                | -5                                      |
| 2       | 01-16-2024 | 8 a.m.     | 2                | -4                                      |
| 3       | 01-19-2024 | 5 p.m.     | 3                | -5                                      |
| 4       | 01-24-2024 | 7 a.m.     | 4                | -13                                     |
| 5       | 01-31-2024 | 7 a.m.     | 3                | -10                                     |
| 6       | 02-07-2024 | 5 p.m.     | 4                | -3                                      |
| 7       | 02-08-2024 | 7 a.m.     | 2                | -6                                      |
| 8       | 02-16-2024 | 7 a.m.     | 4                | -11                                     |
| 9       | 02-21-2024 | 7 a.m.     | 3                | -15                                     |
| 10      | 02-27-2024 | 7 a.m.     | 2                | -1                                      |

For Residential DR, an enrolled device corresponds to a device that was ready to be controlled during an event, yet was not necessarily controlled, i.e., a thermostat that did not have its setpoint reduced. A participating device corresponds to a device that was controlled during an event.

A target of 0.210 MW was set for Residential DR total available DR capacity at the generator in 2024. While new and total available DR capacities are two metrics that are reported separately, this report does not differentiate between them as they are the same during the first year of the pathway. This is due to the fact that new available DR capacity is obtained by subtracting the previous year's total available DR capacity from the evaluation year's total available DR capacity.

## 1.2 Follow-up on Past Evaluation Report Recommendations

The Evaluator evaluated Residential DR in 2023 and issued one improvement recommendation. Table 6 below provides a summary of the implementation status of the recommendation presented in the Executive Summary section of the 2023 report.

**Table 6: Implementation Status of Past Recommendation for Res DR**

| #                 | Recommendation                                                                                                                    | Status | Comments                                                                                                 |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------|--------|----------------------------------------------------------------------------------------------------------|
| 2023 –Res DR – R1 | Ensure that available DR capacity tracked by E1 includes the in-service rate as well as the unitary available DR capacity values. | N/A    | This recommendation is applicable to the DHW Direct Load Control pathway that was not evaluated in 2024. |

## 1.3 Participation History

In 2024, there were 353 participants in Residential DR, with a total of 1,307 enrolled devices.<sup>2</sup> As presented in Figure 1 below, Mysa thermostats represented the largest proportion of installed devices (83%).

**Figure 1: Overview of Residential DR Participation, 2024**

Since participants continued to enroll throughout the season and they could opt out of any event, not all enrolled devices participated in each event. Table 7 below presents the number of devices enrolled in each event. Moreover, connectivity issues meant that not all enrolled participants actually participated in each event; the number of devices that participated is discussed in Subsection 3.2.1 below.

<sup>2</sup> The number of devices used herein is the number of enrolled devices at the time of the last event of the season, as presented in Table 7.

**Table 7: Eco Shift Pilot Device Enrollment per 2023-2024 Event**

| Event # | Date       | Devices Enrolled per Event    |                  |                    |       |
|---------|------------|-------------------------------|------------------|--------------------|-------|
|         |            | Connected EVs and EV Chargers | Mysa Thermostats | Sinopé Thermostats | Total |
| 1       | 01-09-2024 | 17                            | 934              | 140                | 1,091 |
| 2       | 01-16-2024 | 36                            | 947              | 141                | 1,124 |
| 3       | 01-19-2024 | 34                            | 951              | 144                | 1,129 |
| 4       | 01-24-2024 | 35                            | 983              | 145                | 1,163 |
| 5       | 01-31-2024 | 39                            | 1,035            | 170                | 1,244 |
| 6       | 02-07-2024 | 49                            | 1,055            | 170                | 1,274 |
| 7       | 02-08-2024 | 49                            | 1,055            | 170                | 1,274 |
| 8       | 02-16-2024 | 50                            | 1,076            | 171                | 1,297 |
| 9       | 02-21-2024 | 50                            | 1,075            | 171                | 1,296 |
| 10      | 02-27-2024 | 50                            | 1,082            | 175                | 1,307 |

## 2 Residential DR Evaluation Approach

The 2024 Residential DR evaluation comprised a comprehensive impact evaluation. The main objective of the 2024 Residential DR evaluation was as follows:

- › Calculate Residential DR results, namely new and total available DR capacities

The Evaluator identified key research questions aimed at achieving this objective. Table 8 outlines the Residential DR evaluation objectives and maps them to the research questions and methods established by the Evaluator. Each method is described further below.

**Table 8: 2024 Residential DR Evaluation Approach**

| Evaluation Objectives                   | Research Questions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Methodology                                                                                                                                             |

### Tracking Sheet Audit

Prior to performing the available DR capacity calculation review, the Evaluator audited the final 2024 tracking sheet to ensure it was complete and the entered data were consistent. It should be noted that, for Residential DR, E1 did not track results since the Evaluator established the final methodology to be used as part of the current evaluation. Therefore, the tracking sheet audit served to ensure that E1 provided all information needed to establish the savings and that the information was complete and accurate instead of serving to validate tracked results. The results obtained are presented in Appendix I.

### Metering Data Analysis

To establish the available DR capacity generated from Mysa thermostats, the Evaluator analyzed the available participant whole-house consumption meter data and established a unitary available DR capacity value per participant, which was then converted to a unitary available DR capacity per thermostat and multiplied by the number of enrolled thermostats. Whole-house data were preferred to device-level data since they included interactive effects. The detailed methodology and results obtained are presented in Subsection 3.2.2. The 2024-2025 Demand-side Management Measure Assessment<sup>3</sup> (DSM MA) was updated accordingly.

<sup>3</sup> The 2024-2025 DSM MA is a reference document that provides an in-depth review of all necessary parameters to calculate the annual and lifetime gross energy and peak demand savings of most prescriptive measures and some semi-prescriptive measures offered through E1's DSM program portfolio. In addition, the Measure Assessment includes effective useful life values for all measures offered in E1's program portfolio. For the evaluations conducted during the last two years of the 2023-2025 DSM cycle, the Evaluator refers to the values presented in the 2024-2025 DSM MA.

The Evaluator did not assess the available DR capacity for other products included in the Eco Shift Pilot pathway as the number of participants for EV products and batteries were not sufficient to obtain reliable results and the data for Sinopé thermostats were incomplete. For 2024, the Mysa thermostat unitary available DR capacity can be used for Sinopé thermostats since the control strategy was similar and Sinopé setbacks were greater than Mysa setbacks when averaged over all events. It should be noted that, although there were enrolled EVs in 2024, the Evaluator was unable to establish a unitary available DR capacity due to low participation. Indeed, not all enrolled EVs are connected and charging when events are called. Therefore, no available DR capacity was claimed for EVs and batteries in the 2024 evaluation.

## Calculations Using Evaluation Results

Building on all the above methods and collected data, the Evaluator calculated the new and total amount of available DR capacity as per the calculation methodology presented in Section 3 below.

### Note on Margins of Error

For evaluation activities that yield quantitative results based on a sample, the Evaluator typically aimed to achieve a maximum margin of error of 10% at a confidence level of 90%. This means that, if measurements were conducted many times with different samples, the data would be within 10 percentage points above or below the percentage reported 90% of the time. Thus, the margin of error indicates the relative level of precision<sup>4</sup> of a measurement, while its associated confidence level indicates the probability of a measurement falling within the margin of error.

As part of the Residential DR evaluation, the Evaluator calculated the margins of error for the unitary and per-event available DR capacities. Although the entire population of Mysa thermostats was included in the analysis, this was considered a sample since the unitary savings are intended to be used for future program years. The margins of error are listed alongside results in the applicable sections herein. Considering the relatively small number of participants used for Residential DR analyses and the complexity of estimating hourly load profiles due to the variability around consumption patterns, higher margins of error were considered acceptable; the Evaluator ensured that the results were statistically significant. Examples of calculations used to establish margins of error are provided in Appendix II of the 2024 DSM Programs Evaluation Executive Summary document.

---

<sup>4</sup> Precision refers to how reproducible a set of measurements is. Moreover, it does not consider how close the measured values are to the true values; this would refer to accuracy.

## 3 Residential DR Impact Evaluation

The objective of the 2024 Residential DR impact evaluation was to determine new and total available DR capacities.

### 3.1 Tracking Sheet Audit

To ensure program component results were reliably compiled, the Evaluator first performed a tracking sheet audit aimed at verifying the completeness and consistency of the data submitted by E1. It should be noted that, for Residential DR, E1 did not track results since the Evaluator established the final methodology to be used as part of the current evaluation. Therefore, the tracking sheet audit served to ensure that E1 provided all information needed to establish the savings and that the information was complete and accurate instead of serving to validate tracked results. The verification and corrective actions taken by the Evaluator, where applicable, are described in Appendix I.

### 3.2 Demand Response Capacity

For Residential DR, the metric is the available DR capacity that corresponds to the load reduction made available for peak demand events in participant homes. For the Eco Shift Pilot pathway, the Evaluator established a unitary available DR capacity value that was multiplied by the number of participating thermostats to obtain the evaluated available DR capacity. While new and total available DR capacities are two metrics reported separately, no distinction is made between them throughout this report as they are the same during the first year of the pathway. It should be noted that, although there enrolled EVs in 2024, the Evaluator was unable to establish a unitary available DR capacity due to low participation.

#### 3.2.1 In-service Rates

For the Eco Shift Pilot pathway, not all devices participated in each event since participants continued to be registered throughout the season and participants could opt out of any event. Additionally, connectivity issues meant that not all enrolled devices actually participated in each event. Since participants were not removed from the whole-house data analysis if they opted out of an event or had connectivity issues, the in-service rate is directly included in the unitary available DR capacity. Indeed, not removing those participants reduced the average available DR capacity, and this would also have been the case if an in-service rate and a unitary savings that does not encompass an in-service rate had been used. An in-service rate would have been needed if device-level data had been used.

The number of participating devices and the resulting in-service rate are presented in Table 9 below for information purposes.

**Table 9: Eco Shift Pilot Mysa Thermostat In-service Rate per 2023-2024 Event**

| Event # | Date       | Devices Enrolled per Event |                                 |                 |
|---------|------------|----------------------------|---------------------------------|-----------------|
|         |            | Number of Enrolled Devices | Number of Participating Devices | In-service Rate |
| 1       | 01-09-2024 | 934                        | 919                             | 98%             |
| 2       | 01-16-2024 | 947                        | 928                             | 98%             |
| 3       | 01-19-2024 | 951                        | 940                             | 99%             |
| 4       | 01-24-2024 | 983                        | 952                             | 97%             |
| 5       | 01-31-2024 | 1,035                      | 996                             | 96%             |
| 6       | 02-07-2024 | 1,055                      | 1,025                           | 97%             |
| 7       | 02-08-2024 | 1,055                      | 1,020                           | 97%             |
| 8       | 02-16-2024 | 1,076                      | 1,036                           | 96%             |
| 9       | 02-21-2024 | 1,075                      | 1,028                           | 96%             |
| 10      | 02-27-2024 | 1,082                      | 1,061                           | 98%             |
| Average |            | 1,019                      | 991                             | 97%             |

### 3.2.2 Unitary Available DR Capacity

For the Eco Shift Pilot pathway, the available DR capacity was only quantified for Mysa thermostats in the 2024 evaluation. The Evaluator relied on a unitary available DR capacity value, more precisely the average available DR capacity per thermostat. To establish this unitary available DR capacity value, the Evaluator developed a model that predicts the expected average hourly load per participant and then compared the expected and actual hourly loads during events.

## Metering Data Analysis Methodology

After reviewing existing literature to identify the most appropriate baseline methodology for the 2024 evaluation, the Evaluator decided to rely on whole-house consumption data to establish a regression model for the baseline, relying on a model that considers the time of week and outdoor temperature. Whole-house data were preferred to device-level data as they allow for the inclusion of interactive effects such as other heating systems not controlled by participating smart thermostats offsetting the reduced load associated with participating thermostats. Regression models were preferred since they were the most common methodology for similar smart thermostat programs in the jurisdictions reviewed.<sup>5</sup> Moreover, regression models are based on a large dataset that includes datapoints for cold temperatures comparable to those of the events, while using a day-matching approach to establish a baseline may result in not using days that are as cold as the event days. As for the use of time of week, it allows to differentiate the impact of outdoor temperature at each time of the week, which is preferred since the setpoints are likely to be different at different hours of the day and days of the week.

The model used by the Evaluator consists of 168 regression models, i.e. one for each hour of the week. Each regression model establishes a correlation between the average participant hourly load at a given time of the week and the corresponding heating degree days.<sup>6</sup> To do so, all datapoints for a given time of week were grouped together to establish one of the 168 regressions. To obtain reliable results, the Evaluator excluded some participants because they had inconsistent loads, notably participants with EVs and participants that moved during the evaluation period. The Evaluator also excluded some data because of missing or incoherent datapoints. After cleaning the data from the initial 272 households with Mysa thermostats, 199 households were included in the analysis. More details on the methodology, including the data cleaning process and the margin of error calculation, are included in Appendix II. The resulting coefficients for each regression are presented in Appendix III.

## Metering Data Analysis Results

Using the methodology presented above, the Evaluator established the DR capacity made available at each event hour of the 2023-2024 heating season. As mentioned in the introduction, available DR capacity is measured over the first two hours of a DR event. Table 10 below therefore presents the results for the two first hours of each event of the 2023-2024 heating season.

As indicated in red text in Table 10 below, a few of the event hours had negative DR capacity, meaning that participants had a higher load during the event than the expected load in the absence of the event. It should be noted that the service provider intended to include 30 minutes of preheating for Events 6, 7, and 8 (cells highlighted in red in Table 10); however, preheating was incorrectly implemented due to an issue being investigated and occurred during the events instead of before the events, thus resulting in a load higher than the baseline and in negative available DR capacity for the first hour for those events.

| 7                                                          | 02-08-2024 | 7          | -454                      | 250                 |
|                                                            |            | 8          | 559                       | 212                 |
| 8                                                          | 02-16-2024 | 7          | -580                      | 263                 |
|                                                            |            | 8          | 508                       | 234                 |
| 9                                                          | 02-21-2024 | 7          | 337                       | 274                 |
|                                                            |            | 8          | 193                       | 275                 |
| 10                                                         | 02-27-2024 | 7          | 120                       | 201                 |
|                                                            |            | 8          | 113                       | 228                 |
| Average available DR capacity for all events               |            |            | 177                       | 105                 |
| Average available DR capacity excluding Events 6, 7, and 8 |            |            | 259                       | 165                 |

While not all hours of all events resulted in statistically significant available DR capacity, the average available DR capacity observed across all events was statistically significant.

To visualize the impact of each event, the Evaluator created charts illustrating the expected and actual load for each event day. Figure 2 below illustrates Event 4, which lasted four hours, while the other charts are presented in Appendix IV. The blue line represents the expected load in the absence of an event while the green line represents the actual load during the event day. As there was no preheating for Event 4, the load reduction starts in the first event hour and continues throughout the event. A slight load increase can be observed after the event ends, which is expected when thermostat setpoints are returned to normal.

Figure 2: Event 4 Expected and Actual Loads

### Unitary Available DR Capacity

As outlined in Table 10 above, the average available DR capacity across all events was 177 W per household. The household data included in the metering analysis were used to establish an average of 4.5 thermostats per household. Using this average and the average available DR capacity per household, the Evaluator established a unitary available DR capacity of **39.4 W per thermostat**. The Evaluator used that value for the 2023-2024 period.

If E1 and the service provider are able to ensure that no preheating implementation error occurs in the future, the Evaluator expects the average available DR capacity to increase. **Therefore, the Evaluator recommends that Eco Shift Pilot data be gathered and analyzed again in 2025.**

With that in mind, the Evaluator established an expected unitary available DR capacity for informational purposes only. Using the average available DR capacity per household, excluding Events 6, 7, and 8 (highlighted in light red in Table 10 above), and the average number of thermostats per participant, the Evaluator established an expected unitary available DR capacity of 57.7 W per thermostat. This value represents the unitary available DR capacity that should be used for program tracking assuming preheating issues are resolved. This value was not used to obtain the 2023-2024 evaluated savings since it does not represent the savings achieved for all events for the evaluated year.

### 3.2.3 Interactive Effects

In a home, interactive effects occur when the implementation of energy efficiency products has an impact on the energy consumption of other elements such as heating and cooling. For the Eco Shift Pilot pathway, all interactive effects from reducing smart thermostat setpoints are included in the evaluation analysis since it is based on whole-house metering data. The Evaluator preferred participant whole-house consumption data (advanced metering infrastructure [AMI]) to device-level data since the former allows for the inclusion of interactive effects from equipment such as other heating systems (e.g. heat pumps) not controlled by participating smart thermostats and offsetting the reduced load associated with participating thermostats.

### 3.2.4 Effective Useful Life

Although no electrical energy savings are expected from DR initiatives, the Evaluator established an EUL value since the available DR capacity can persist over time. For the Eco Shift Pilot pathway, an EUL value of one year should be used with total available DR capacity since participation includes all active participants, not only new participants; therefore, the available DR capacity of a participant will be counted each year and does not need to be extrapolated over its lifetime. With no data yet available on how long a participant might continue in the program, an EUL of one year should also be used for new DR capacity.

### 3.2.5 Evaluated New and Total Available DR Capacities

Available DR capacity is obtained by multiplying the number of controlled thermostats by the unitary available DR capacity value as presented in the equations below.

$$\text{Available DR Capacity} = \text{Number of Thermostats} \times \text{Unitary Available DR Capacity}$$

Table 11 below presents the new and total available DR capacities results for Residential DR in 2024. While new and total available DR capacities are two metrics reported separately, no distinction is made between both throughout this report as they are equal due to this being the first year of the pathway. In 2024, the new and total available DR capacities amounted to 0.057 MW at the generator.

The available DR capacity at the generator was estimated using the residential line loss factor. Line loss factors correspond to the values submitted to the Nova Scotia Utility and Review Board (NSUARB) as part of the 2014 Cost of Service Study Progress Update.<sup>7</sup>

**Table 11: Evaluated 2024 Residential DR New and Total Available DR Capacities**

|                                                      | Results                  |
|------------------------------------------------------|--------------------------|
| <b>Number of Enrolled Thermostats</b>                | <b>1,257<sup>8</sup></b> |
| Unitary Available DR Capacity (Watts per thermostat) | 39.4                     |
| <b>Available DR Capacity – at the Meter (MW)</b>     | <b>0.050</b>             |
| Line Loss Factor                                     | 1.1466                   |
| <b>Available DR Capacity – at the Generator (MW)</b> | <b>0.057</b>             |

If preheat implementation errors had not occurred, Residential DR would have generated 0.083 MW in available DR capacity at the generator. This value was calculated by multiplying the unitary available DR capacity value obtained when excluding events 6, 7, and 8 by the number of units and the line loss factor.

<sup>7</sup> Nova Scotia Utility and Review Board, Matter M06555, 2014 Cost of Service Study Progress Update, Exhibit N-2.09, Appendix I1.

<sup>8</sup> The number of units used herein is the number of Mysa and Sinopé thermostats enrolled at the time of the last event of the season, as presented in Table 7.

Figure 3 outlines the net evaluated and targeted available DR capacity.

**Figure 3: 2024 Residential DR Targets and Evaluated Available DR Capacity**

## 4 Residential DR Key Findings and Recommendations

As mentioned previously, the main objective of the 2024 Residential DR evaluation was as follows:

- › Calculate Residential DR results, namely new and total available DR capacities

This section provides the Evaluator's key findings in relation to this objective.

### **2024 Res DR-Finding: Residential DR did not achieve its total available DR capacity target.**

In 2024, Residential DR new and total available DR capacities both amounted to 0.057 MW at the generator, thus not reaching the planned total available DR capacity of 0.210 MW.

### **2024 Res DR-Finding: Mysa thermostats were the most popular devices in Residential DR, representing 83% of all registered devices.**

In 2024, there were 353 participants in Residential DR, with a total of 1,307 enrolled devices composed of 1,082 Mysa thermostats, 175 Sinopé thermostats, and 50 EVs or EV chargers. Since participants continued to register throughout the season, the numbers presented above represent devices enrolled by the last event of the season. However, opted out participants and connectivity issues meant that not all enrolled devices actually participated in each event; of the enrolled Mysa thermostats, an average of 97% participated during the events.

### **2024 Res DR-Finding: Residential DR available DR capacity was established using a regression model that considers the time of week and outdoor temperature and uses whole-house consumption data.**

The Evaluator decided to rely on whole-house consumption data to establish a regression model for the baseline, relying on a model that considers the time of week and outdoor temperature. Whole-house data were preferred to device-level data as the former allows for the inclusion of interactive effects from equipment such as other heating systems not controlled by participating smart thermostats offsetting the reduced load associated with participating thermostats. As for the time of week method, it allows to differentiate the impact of outdoor temperature at each time of the week. The resulting 168 regression models provided sufficient accuracy with margins of error under 3%. The Evaluator plans to continue using the same methodology to calculate unitary savings for thermostats in future years.

### **2024 Res DR-Finding: Preheating implementation issues prevented the program from reaching its full potential during a few events, resulting in lower DR capacity than expected.**

Although the service provider intended to include 30 minutes of preheating for Events 6, 7, and 8, preheating was incorrectly implemented and occurred during the events instead of before the events, thus resulting in negative available DR capacity for the first hour of those events.

If E1 and the service provider are able to refine the implementation process to avoid this issue, the Evaluator expects the average available DR capacity to increase. Assuming that preheat implementation errors will not occur again in future years, E1 can track available DR capacity during the next heating season using a unitary available DR capacity of 57.7 W per thermostat, which corresponds to the average available DR capacity when excluding events with a preheat implementation error. In comparison, a unitary available DR capacity value of 39.4 W per thermostat was used in this evaluation.

**2024 Res DR Recommendation 1: Gather and analyze the Eco Shift Pilot data again in 2025 to improve the unitary available DR capacity value accuracy and ensure it is consistent over multiple years.**

## 5 BNI DR Overview

This section describes the Business, Non-profit, and Institutional (BNI) Demand Response (DR) program component, follows up on past evaluation recommendations, and provides an overview of BNI DR participation history.

### 5.1 BNI DR Description

In 2023, E1 officially launched the BNI DR program component. Since the fall of 2020, E1 implemented several pilot initiatives focused on reducing demand during the Nova Scotia peak period. One of them was the DR Aggregator Pilot launched in the fall 2022, which is herein considered a pathway in the BNI DR program component.

Through the DR Aggregator pathway, E1 hires aggregators that subscribe groups of BNI customers that can reduce their load upon request. While some participants were recruited through a different aggregator, Parsons Inc. was the aggregator for the DR Aggregator Pilot for the period covered by this evaluation. When NS Power calls DR events, aggregators either remotely control some energy consuming systems in participant buildings or they contact participants to deploy their load reduction procedure that was developed with support from their aggregator. The actions taken to reduce loads typically include shutting down electricity consuming systems such as space heating or cooling (sometimes accompanied by pre-heating or pre-cooling), ventilation, water heating, or lighting. The event scheduling criteria are presented in Table 12.

**Table 12: DR Aggregator Event Criteria**

| Criteria                  | Requirement                                                                                                                                                                         |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Event Season              | Winter is from December through February.                                                                                                                                           |
| Event Windows             | From 7:00-11:00 am and 5:00-9:00 pm, Monday to Friday excluding holidays, during winter.                                                                                            |
| Event Initiation Criteria | Events are called based on NS Power's day ahead forecasting of times of high load, often corresponding with colder temperatures.                                                    |
| Number of Events          | Maximum of 12 events per season.                                                                                                                                                    |
| Event Durations           | Maximum event duration of 4 hours.<br>All events must be entirely contained within the event windows.                                                                               |
| Event Frequency           | No more than 1 event called per day per participant.<br>No more than 3 events called within any given week (Monday to Friday).<br>No more than 2 events called on consecutive days. |
| Event Notification        | NS Power provides notice to Parsons Inc. by 4:00 pm the day before an event is scheduled.                                                                                           |

As presented in Table 13 below, NS Power called 10 events during the 2023-24 winter peak season.

**Table 13: Summary of Event History**

| Month                                                                                                                                                                                                  | Number of Morning Events | Number of Evening Events | Total Number of Events | Average Length of Events (Hours) |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|--------------------------|------------------------|----------------------------------|
| December                                                                                                                                                                                               | 0                        | 0                        | 0                      | N/A                              |
| January                                                                                                                                                                                                | 3                        | 2                        | 5                      | 2.8                              |
| February                                                                                                                                                                                               | 4                        | 2                        | 5                      | 3                                |
| Total                                                                                                                                                                                                  | 7                        | 4                        | 10*                    | 2.9                              |
| * One event in February occurred during two time windows on the same day, one in the morning and one in the evening. Participants were contacted for only the morning or evening portion of the event. |                          |                          |                        |                                  |

BNI DR was aimed at achieving 7.030 MW in total available DR capacity at the generator in 2024.

Throughout this report, **enrolled** available DR capacity corresponds to the potential available DR capacity estimated by the aggregator when a participant is recruited, i.e. before participating in the program. **Tracked** available DR capacity corresponds to the available DR capacity established by E1 based on metering data, while **evaluated** available DR capacity corresponds to the available DR capacity established by the Evaluator.

## 5.2 Follow-up on Past Evaluation Report Recommendations

The Evaluator evaluated BNI DR for the first time during the 2022-2023 pilot season and issued improvement recommendations. Table 14 below provides a summary of the implementation status of each recommendation presented in the Executive Summary section of the 2023 report.

**Table 14: Implementation Status of Past Recommendation for BNI DR**

| #                  | Recommendation                                                                                                            | Status      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|---------------------------------------------------------------------------------------------------------------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2023 – BNI DR – R1 | Use an additive same-day adjustment factor to establish the baseline load instead of a scalar same-day adjustment factor. | Complete    | E1 updated their methodology to use an additive adjustment factor. Scalar adjustments are only used in some instances of reviewed projects with weather driven loads.                                                                                                                                                                                                                                                                                                                                                                     |
| 2023 – BNI DR – R2 | Establish enrolled capacity based on test events when feasible.                                                           | In progress | E1 will establish enrolled capacity based on test events when feasible. Program staff will recommend test events for new participants. Returning participants who wish to add capacity will be reassessed and complete testing will be recommended. For participants who do not complete a test event, program staff will review the engineering calculations used to determine enrolled capacity to ensure they are realistic. A few test events occurred, but none were conducted to establish enrolled capacity for 2024 participants. |
| 2023 – BNI DR – R3 | Determine which participants are best suited for morning events only, evening events only, or morning and evening events. | In progress | E1 identified participants best suited for morning and/or evening events. Program staff developed morning and evening platoons prior to the end of the 2023/24 season and will continue this practice for the 2024/25 season. When two events will be called on the same day, the platoons will be used to call events based on each participant's potential, and enrolled capacity will be established based on the selected time of day. Events will be called for all participants when there will be only one event in a day.         |

### 5.3 Participation History

As presented in Figure 4 below, BNI DR had a total of 76 participating facilities in 2024, a 744% increase compared to the nine facilities from 2023. Each BNI DR participant has at least one NS Power meter enrolled in curtailment events, although some participants have multiple enrolled meters. In 2024, there were a total of 93 participating meters. Herein, a project refers to a meter. The available DR capacity per participant decreased from 263 kW in 2023 to 106 kW in 2024. Given last year was the first year of the pilot program, it is expected that the average DR capacity per participant decreased this year since efforts last year were only focused on a few large participants while many smaller participants were added this year.

**Figure 4: Overview of BNI DR 2024 Participation**

### Participation in Events

Based on the review of 30 projects, it was found that participants did not participate in events around 31% of the time. In conducting project reviews, participants with a lower available DR capacity were found to have participated in fewer events than those with a higher available DR capacity. Non-participation was considered to have been when there was no substantial decrease in demand for a participant during an event or if the event occurred outside of facility operational hours. When considering the participation rate of the reviewed projects and extrapolating this ratio to all projects, the average number of meters participating in an event was established at 64.

Also, in response to a recommendation made in the 2023 evaluation, projects were categorized as being best suited to participate in morning events or evening events. Of the 93 projects, 74 were considered to be best suited for morning participation, and 19 were considered to be best suited for evening participation. Using those categories, events were not called for all projects in two instances. For one morning event, only morning-suited projects were called to participate. For the other event where the categories were used, both a morning and evening event were called and projects participated in only one of them based on their category.

## 6 BNI DR Evaluation Approach

The 2024 BNI DR evaluation comprised a comprehensive impact evaluation. The main objective of the 2024 BNI DR evaluation was as follows:

- › Calculate BNI DR results, namely new and total available DR capacities

The Evaluator identified key research questions aimed at achieving this objective. Table 15 outlines the BNI DR evaluation objective and maps it to the research questions and methods established by the Evaluator. Each method is described further below.

**Table 15: 2024 BNI DR Evaluation Approach**

| Evaluation Objectives                                                 | Research Questions                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Methodology                                                                                                                                             |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|

### Tracking Sheet Audit

Prior to performing the available DR capacity calculation review, the Evaluator audited the final 2024 tracking sheet to ensure it was complete and the entered data were consistent. The results obtained are presented in Appendix VI.

### Project Reviews with Meter Data Analysis

E1 staff sampled and reviewed a total of 30 projects to establish tracked available DR capacity. The sample was stratified so that the 20 projects generating the largest amount of tracked available DR capacity were all reviewed and then a second stratum of ten randomly selected projects among the smaller projects were also reviewed. This stratified approach minimizes the sampling margin of error on adjustment ratios since there is effectively no margin of error on the strata that includes large projects and represents 83% of all available DR capacity.

The Evaluator reviewed all 30 projects that were reviewed by E1 staff and validated all adjustments that were made beyond last year's M&V methodology to obtain revised baseline demand, same-day adjustments, and total demand response capacity. These project reviews served both to establish the evaluated available DR capacity based on the Evaluator review findings and to validate the appropriateness of the new M&V rules used by E1 to review BNI DR projects. The results obtained are presented in Subsection 3.2.1 below.

## Calculations Using Evaluation Results

Building on all the above methods and collected data, the Evaluator calculated the new and total amount of available DR capacities.

### Note on Margin of Error

For evaluation activities that yield quantitative results based on a sample, the Evaluator aimed to achieve a maximum margin of error of 10% at a confidence level of 90%. This means that, if measurements were conducted many times with different samples, the data would be within 10 percentage points above or below the percentage reported 90% of the time. Thus, the margin of error indicates the relative level of precision<sup>9</sup> of a measurement, while its associated confidence level indicates the probability of a measurement falling within the margin of error.<sup>10</sup>

For BNI DR, a margin of error was calculated for the adjustment ratio obtained from the project reviews as presented in Subsection 7.2.1 below.

---

<sup>9</sup> Precision refers to how reproducible a set of measurements is. However, it does not consider how close the measured values are to the true values; this would refer to accuracy.

<sup>10</sup> As part of this evaluation, the confidence levels and margins of error only take random sampling errors into account; they do not reflect non-sampling errors or biases such as data entry errors, inaccurate responses from respondents, or the inability to contact certain people.

## 7 BNI DR Impact Evaluation

The main objective of the 2024 BNI DR impact evaluation was to determine new and total available DR capacities. In addition, the Evaluator validated the correct application with the M&V methodology approach recommended by the Evaluator in the 2023 evaluation and assessed the appropriateness of the new M&V rules.

### 7.1 Tracking Sheet Audit

To ensure program component results were reliably compiled, the Evaluator first performed a tracking sheet audit aimed at verifying the completeness and consistency of the data submitted by E1. The verification and corrective actions taken by the Evaluator, where applicable, are described in Appendix VI. The tracked available DR capacity results presented in this report therefore refer to the corrected tracked available DR capacity obtained by the Evaluator.

### 7.2 Demand Response Capacity

For BNI DR, the evaluated metric is referred to as available DR capacity and corresponds to the load reduction made available for peak demand events in participating businesses.

#### 7.2.1 Project Reviews and Meter Data Analysis

For the Aggregator pathway, available DR capacity is established by comparing the predicted loads (baseline) to the actual loads during DR events using meter data. Baselines for DR events are established based on an average load during similar days prior to an actual event. More precisely, the baseline was the average load during the same hours of the event for the six days with the highest loads among the ten eligible days prior to an event (top six-of-ten), to which a same-day additive adjustment factor was applied. The eligible days correspond to non-holiday weekdays excluding event days and days preceding an event. The same-day additive adjustment factor is the difference between the average load of the selected baseline days for a two-hour window starting three hours before the event (e.g. the load between 2 pm and 4 pm for an event starting at 5 pm) and the load on the event day for the same hours. As recommended in the 2023 evaluation, E1 changed their M&V methodology to use an additive adjustment factor in place of a scalar one.

While the methodology presented in the previous paragraph is the foundation of how available DR capacity is obtained for the Aggregator pathway, E1 also reviewed the results for a stratified sample of 30 projects including the 20 projects with the most available DR capacity (stratum 1 using a census approach) and another 10 randomly selected projects (stratum 2). The adjustment ratio established for stratum 2 was extrapolated to the calculated available DR capacity of all smaller projects, including those that were not reviewed.

E1 reviews served to establish the tracked available DR capacity, thus the tracked available DR capacity differs from the values directly obtained from applying the Aggregator pathway calculation methodology. The E1 review process follows guidelines that were laid out in a document titled BNI DR Baseline Considerations, which is provided in Appendix VIII.

The Evaluator conducted project reviews to verify that the calculation approach and project review guidelines established in the previous evaluation and the BNI DR Baseline Consideration document were followed by E1 as well as to assess the appropriateness of the new rules set out in the BNI DR Baseline Consideration document. The projects reviewed by the Evaluator were the same as those reviewed by E1, i.e. the 20 largest projects from stratum 1 and the same sample of 10 random projects from stratum 2. The template used for project reviews is provided in Appendix IX.

## Project Review Findings

The most frequent adjustment made by E1 to the available DR capacity calculation was to set the available DR capacity to zero due to non-participation in events. If no obvious load shed was observable for an event with either positive or negative available DR capacity, the available DR capacity was set to zero. That was notably the case for all events with negative available DR capacity. Events that occur outside of a building's operational hours, as determined with the building load profile, were also considered to have been from non-participants and had available DR capacity set to zero. These adjustments were made consistently by E1 and were considered by the Evaluator as acceptable practices in determining available DR capacity, yet they are not explicitly stated in the BNI DR Baseline Consideration document. **The Evaluator recommends explicitly stating how and when to set available DR capacity to zero due to non-participation.** While the Evaluator agreed with all changes related to non-participation made by E1, the available DR capacity of three additional instances were set to zero by the Evaluator. The Evaluator also adjusted the available DR capacity for one event that occurred around the end of a facility's daily operational hours so that only the available DR capacity observable during the portion of the event that occurred within the facility operational hours was considered, thus setting to zero the available DR capacity for the portion of the event that occurred outside of operational hours.

The Evaluator noticed that, for some events, E1 excluded the event from the average available DR capacity calculation due to incorrect or missing metering data because of technical issues. Other events were also excluded by E1 since no event was called for some projects that were identified as morning-only or evening-only projects. E1 assigned projects to these groups in answer to a recommendation from the 2023 evaluation. **The Evaluator agrees with excluding events in these circumstances, but this is not explicitly stated in the BNI DR Baseline Consideration document and therefore should be added to it.**

Another common adjustment made by E1 was to move the lookback window used to determine same-day adjustment factors. Moving the lookback window is allowed as per BNI DR Baseline Considerations and is intended to account for any abnormalities that occur in event day consumption. This adjustment was appropriately applied by E1 in most cases, but the Evaluator corrected it for some events. For some buildings, the Evaluator noted that lookback windows were moved by E1 for some events with no abnormal load during the lookback windows because it visually improved the baseline estimate, yet such change was not made for other events from the same time of day. For example, the lookback window was moved to after the event for some 7 am events of a given project with a consistent load profile because using the operating load provided a better estimated baseline load, yet the change was not made for all 7 am events. The Evaluator considers it acceptable to move the lookback window for events, even if there is no abnormality in consumption, when the lookback window does not accurately capture a facility daily load, such as if the lookback window occurs prior to the facility opening for the day, although that change should be made consistently. **The Evaluator corrected this by ensuring lookback windows were consistently adjusted in these cases and recommends that this rule be added to the BNI DR Baseline Considerations for same time of day events unless the adjustment is due to abnormal consumption.**

Globally, the Evaluator found that E1 project reviews were appropriate and followed E1 guidelines.

## Available DR Capacity

In their compilation, E1 automatically set the available DR capacity to zero when an event resulted in negative available DR capacity. The Evaluator agreed with this compilation approach since all reviewed events that had negative available DR capacity were adjusted to zero by both E1 and the Evaluator in the project reviews. It is thus reasonable to assume that all non-reviewed projects with negative available DR capacity would be adjusted to zero if they were reviewed. Adjustment ratios were therefore calculated by comparing the calculated available DR capacity with negative values set to zero to the reviewed values.

It should be noted that the 20 largest projects to be reviewed were identified before the negative available DR capacity values were replaced by zero since E1's decision to set those values to zero resulted from the findings of project reviews. This resulted in two projects that should have been included in the 20 largest projects to not be selected for project reviews. **In the future, the sampling should be made after negative values are set to zero.**

Table 16 below presents the available DR capacity following the project reviews conducted by E1 and the Evaluator. As highlighted in Table 16, the Evaluator project reviews resulted in only small differences compared to E1 project reviews, with 1% less available DR capacity for stratum 1 projects and 1% more for stratum 2 projects.

**Table 16: Reviewed Available DR Capacity**

| Metric                                           | Stratum 1 Projects |                  |                | Stratum 2 Projects |                  |                |
|--------------------------------------------------|--------------------|------------------|----------------|--------------------|------------------|----------------|
|                                                  | E1 Values          | Evaluator Values | Difference (%) | E1 Values          | Evaluator Values | Difference (%) |
| Available DR Capacity Before Project Review (kW) | 6,167              | 6,167            | N/A            | 419                | 419              | N/A            |
| Adjustment Ratio                                 | 1.00               | 0.99             | N/A            | 0.72               | 0.73             | N/A            |
| Available DR Capacity After Project Review (kW)  | 6,157              | 6,124            | -1%            | 302                | 305              | 1%             |

Table 17 presents the adjustment ratios for each stratum as well as the overall adjustment ratio that was applied to all projects to determine evaluated available DR capacity.

**Table 17: Evaluated Adjustment Ratios**

| Stratum   | Adjustment Ratio | Margin of Error | Percentage of Total Available DR Capacity |
|-----------|------------------|-----------------|-------------------------------------------|
| Stratum 1 | 0.99             | 0%              | 81%                                       |
| Stratum 2 | 0.73             | 16%             | 19%                                       |
| Overall   | <b>0.93</b>      | <b>7%</b>       | <b>100%</b>                               |

Overall, the Evaluator project reviews resulted in an adjustment ratio of 0.93 with a margin of error of 7%.

Since it is only the second year of the Aggregator pathway, the Evaluator expects improved participation in events in future years, thus fewer events being adjusted to zero available DR capacity. Therefore, the Evaluator recommends conducting the same project reviews process again in future years. In a few years, E1 could consider reducing the frequency of this review process if the adjustment ratio is stable.

## 7.2.2 Interactive Effects

In a building, interactive effects occur when the implementation of energy efficiency products has an impact on the energy consumption of other elements such as heating and cooling. For the Aggregator pathway, interactive effects are included in the available DR capacity calculation since meter data encompass whole building consumption.

## 7.2.3 Effective Useful Life

Although no energy savings were expected under the Aggregator pathway, the Evaluator established an effective useful life (EUL) value to express for how many years available DR capacity might persist, i.e. as long as participants continue with the program. For the Aggregator pathway, an EUL value of one year should be used for total available DR capacity since participation includes all active participants, not only new participants; therefore, the available DR capacity of a participant is counted each year and does not need to be extrapolated over its lifetime. The average number of winters that participants subscribe to the pathway should be used as the EUL value with new available DR capacity. With no data yet available on how long a participant might continue in the program, an EUL of one year should also be used for new DR capacity.

## 7.2.4 Evaluated New and Total Available DR Capacities

Table 18 below presents the new and total available DR capacity results of BNI DR for 2024. For BNI DR, the new available DR capacity was defined as the increase in available DR capacity compared to the previous year. This includes changes in available DR capacity from previous participants and available DR capacity generated by new participants. As presented in Table 18, new and total available DR capacities respectively amounted to 5.669 MW and 8.034 MW at the generator.

The available DR capacity at the generator was estimated using the appropriate line loss factors for each participant based on the relevant rate code. The values presented in Table 18 are therefore weighted average line loss factors. The line loss factors correspond to the values submitted to the Nova Scotia Utility and Review Board (NSUARB) as part of the 2014 Cost of Service Study Progress Update.<sup>11</sup>

**Table 18: Evaluated 2024 BNI DR Available DR Capacity**

|                                                                                                                                                                    | Results                   |                             |

**Figure 5: 2024 BNI DR Targets and Evaluated Available DR Capacity**

## Comparison of Enrolled and Evaluated Available DR Capacity

Table 19 presents the difference between enrolled DR capacity and evaluated DR capacity.

**Table 19: Evaluated 2024 BNI DR Available DR Capacity**

| Metric                          | Stratum 1 Projects | Stratum 2 Projects | Overall |
|---------------------------------|--------------------|--------------------|---------|
| Enrolled DR Capacity (MW)       | 5.699              | 6.525              | 12.224  |
| Evaluated DR Capacity (MW)      | 6.124              | 1.463              | 7.587   |
| Percentage Achieved of Estimate | 107%               | 22%                | 62%     |

In a few years, available DR capacity is expected to be a reliable resource to reduce electric system loads during peak events; thus, it is important to establish proper estimates of expected available DR capacity (enrolled DR capacity).

As presented in Table 19 above, stratum 1 projects had higher available DR capacity than estimated, while stratum 2 projects had 78% lower available DR capacity than estimated. Overall, participants achieved 62% of estimated demand reductions. The largest reason for participants not achieving their enrolled available DR capacity was due to non-participation in events.

## 7.3 Program Realization Rate

Table 20 below compares the available DR capacity established through this evaluation to the value in the 2024 tracking sheet. The realization rates, representing the ratio of evaluated available DR capacity to tracked available DR capacity, were established at 99% and 100% for new and total available DR capacities respectively.

**Table 20: Comparison of 2024 BNI DR Tracked and Evaluated  
New and Total Available DR Capacities at the Generator**

|                                     | Available DR Capacity |      |      |
|-------------------------------------|-----------------------|------|------|
|                                     | Value                 | Unit |      |
| New Available DR Capacity           |                       |      |      |
| Available DR Capacity Tracked by E1 | 5.702                 | MW   | 99%  |
| Evaluation Results                  | 5.669                 | MW   |      |
| Total Available DR Capacity         |                       |      |      |
| Available DR Capacity Tracked by E1 | 8.067                 | MW   | 100% |
| Evaluation Results                  | 8.034                 | MW   |      |

Evaluated new and total available DR capacities were slightly lower than the values tracked by E1. The differences are due to the adjustments made during project reviews as discussed in Subsection 3.2.1 above.

## 8 BNI DR Key Findings and Recommendations

As mentioned previously, the main objective of the 2024 BNI DR evaluation was as follows:

- › Calculate BNI DR results, namely new and total available DR capacities

This section provides the Evaluator's key findings and recommendations in relation to this objective.

### **2024 BNI DR-Finding: BNI DR exceeded the available DR capacity target.**

Total available DR capacity at the generator amounted to 8.034 MW that included 5.669 MW of new DR capacity. Therefore, BNI DR exceeded its target of 7.030 MW in total available DR capacity.

### **2024 BNI DR-Finding: BNI DR participation substantially increased compared to last year, while average available DR capacity per participant decreased.**

Participation grew over 700% from nine participants last year to 76 participants this year. The available DR capacity per participant decreased from 263 kW in 2023 to 106 kW in 2024.

### **2024 BNI DR-Finding: Overall, the BNI DR available DR capacity calculation guidelines developed by E1 were appropriate and generally followed.**

The Evaluator project reviews resulted in only a small difference in available DR capacity compared to the value obtained by E1 after their project reviews. This is the result of the Evaluator mostly agreeing with the changes made by E1. Nonetheless, the Evaluator identified a few gaps in the BNI DR Baseline Considerations document to properly cover all the different adjustments encountered through the project reviews.

While the Evaluator agreed with setting the available DR capacity to zero for events with no obvious participation, including events with negative available DR capacity, events with no observable load reduction on the plotted daily load, or events happening outside building operating hours, the baseline adjustment guidelines do not clearly define how to identify building operating hours. Additionally, the guidelines should mention that, for events occurring partly during and outside of building operating hours, the available DR capacity for the portion of the time outside building operating hours should be set to zero.

In some cases, the methodology to calculate a same-day adjustment did not accurately adjust the expected load, such as when the lookback window captures an abnormal load or hours outside operating hours. In these circumstances, it is acceptable to move the adjustment window to a different time during the day. However, when this change is made for another reason than abnormal consumption level, such a change should be made consistently for all events of a given participant for which the circumstance applies.

### **2024 BNI DR Recommendation 1: Update the BNI DR Baseline Considerations document to properly address all situations encountered through the project reviews.**

- › Clearly define how to identify building operating hours and when to set the available DR capacity to zero.
- › Ensure that lookback windows are moved consistently across all similar events unless they are moved due to an abnormal load.
- › Clearly state in the document that certain events may be excluded on a per-participant basis due to missing AMI metering data because of technical issues or events not being called for participants identified as morning-only or evening-only participants.

**2024 BNI DR-Finding: E1's sampled project review allowed establishing a reliable adjustment ratio at the program level to obtain accurate tracked available DR capacity.**

The evaluation revealed that reviewing and adjusting the results for a stratified sample of projects (20 projects with the largest available DR capacity and 10 randomly selected projects among the others) allowed to establish reliable evaluated available DR capacity. Indeed, the Evaluator project reviews resulted in an adjustment ratio of 0.93 with margin of error below 10%. The Evaluator also noted that, in future, sampling should be made after negative values are set to zero.

**2024 BNI DR Recommendation 2: In the next evaluation, continue to use project reviews to establish tracked and evaluated available DR capacities.**

**2024 BNI DR-Finding: The evaluated available DR capacity determined by the Evaluator was slightly lower than the available DR capacity tracked by E1.**

The evaluated new and total available DR capacities were 1% and less than 1% lower than the values tracked by E1 respectively. The differences are due to the adjustments made through the project reviews.

## CONCLUSION

Table 21 presents the participation levels and evaluated new and total available DR capacity for each program component and for the Demand Response program as a whole.

**Table 21: Overall 2024 Demand Response Participation and Evaluated Results**

|                       | Participation Level |              | Evaluated Results |      |
|-----------------------|---------------------|--------------|-------------------|------|
|                       | Value               | Unit         | Value             | Unit |
| <b>Residential DR</b> |                     |              |                   |      |
| New DR Capacity       | 353                 | Participants | 0.057             | MW   |
| Total DR Capacity     | 353                 | Participants | 0.057             | MW   |
| <b>BNI DR</b>         |                     |              |                   |      |
| New DR Capacity       | 70                  | Participants | 5.669             | MW   |
| Total DR Capacity     | 76                  | Participants | 8.034             | MW   |
| <b>Total</b>          |                     |              |                   |      |
| New DR Capacity       |                     |              | 5.726             | MW   |
| Total DR Capacity     |                     |              | 8.091             | MW   |

Figure 6 and Figure 7 below respectively illustrate the new and total evaluated available DR capacity for each program component, Demand Response as a whole, as well as whether targets were achieved in 2024. The program exceeded the planned total available DR capacity even though Residential DR fell short of its target. BNI DR was the largest contributor to total program available DR capacity.

## APPENDIX I

### Residential DR: Tracking Sheet Audit

---

This document presents the detailed results of the tracking sheet audit performed by the Evaluator, which was aimed at:

- › Verifying that all data fields required for the evaluation were included and filled out in the tracking sheet submitted by EfficiencyOne (E1)

For Residential DR, E1 did not track results (available DR capacity) since the Evaluator established the final methodology to be used as part of the current evaluation. Instead, E1 provided spreadsheets with participants' raw thermostat and whole-house consumption data, which were herein considered the tracking sheets. Instead of validating tracked results as done in typical tracking sheet audits, the Evaluator audited the tracking sheets to ensure that E1 provided all the information needed to establish savings and that the information was complete and accurate. After review, the spreadsheets provided by E1 were sufficient for the Evaluator to calculate Residential DR results.

## APPENDIX II

# Residential DR: Detailed Metering Data Analysis Methodology

This appendix summarizes the methodology used by the Evaluator to establish the available DR capacity as part of the 2024 evaluation of Residential DR.

For the Eco Shift Pilot pathway, available DR capacity was only quantified for Mysa thermostats in the 2024 evaluation. The Evaluator relied on a unitary available DR capacity value, more precisely the average available DR capacity per thermostat. To establish this available DR capacity value, the Evaluator developed a model that predicts the expected average hourly load per participant and then compared the expected and actual hourly loads during events. The average available DR capacity per household obtained from the previous step was then divided by the average number of thermostats per household to calculate a unitary available DR capacity. The average number of thermostats per household was obtained using the number of enrolled devices and number of participants specific to each event. The Evaluator used participant whole-house consumption data (advanced metering infrastructure [AMI]) to quantify the available DR capacity. Whole-house data were preferred to device-level data as they allow for the inclusion of interactive effects from equipment such as other heating systems not controlled by participating smart thermostats offsetting the reduced load associated with participating thermostats.

### Form of the Regression

After reviewing existing literature to identify the most appropriate baseline methodology for this evaluation, the Evaluator decided to use a regression model that considers the time of week and outdoor temperature to establish a baseline. Such models take into account the impact of outdoor temperature on electricity consumption, thus creating a predictive model that can be extrapolated using the known temperature at the time of events while also recognizing that electricity consumption in a household varies based on other factors. Since the population consists only of residential households, the influence of such factors is expected to be similar on the entire population at a given time of the week, hence the creation of the time of week and temperature model. Regression models were preferred since they are the most common methodology for similar smart thermostat programs in the jurisdictions reviewed.<sup>1</sup> Moreover, regression models are based on a large dataset that includes datapoints for cold temperatures comparable to those of the events, while using previous similar days to establish a baseline may result in not using days that are as cold as the event days. As for the use of time of week, it allows to differentiate the impact of outdoor temperature at each time of the week, which is preferred since the setpoints are likely to be different at different hours of the day and days of the week.

The model used by the Evaluator consists of 168 regression models, i.e. one for each hour of the week. Each regression model establishes a correlation between the average participant hourly load at a time of week and the corresponding heating degree days.<sup>2</sup> To do so, all datapoints for a given time of week were grouped together to establish one of the 168 regressions. For example, if the dataset includes 20 participants and each participant's subset includes 10 datapoints for "Monday at 8 a.m.", the regression for "Mondays at 8 a.m." would be built based on 200 datapoints. Each of the 168 regressions is represented by the equation below; the coefficients ( $\alpha_{D,H}$  and  $\beta_{D,H}$ ) obtained by the Evaluator for each regression are presented in Appendix III.

$$\text{Baseline } kW_{D,H} = \alpha_{D,H} \times x^* + \beta_{D,H}$$

Where:

- ›  $\text{Baseline } kW_{D,H}$  is the calculated baseline load in kW on a specified day of week (D) and hour of day (H), for a given temperature.
- ›  $D, H$  is the time of the week where D is from 1 to 7 (Sunday to Saturday) and H is from 00 to 24 (midnight to 11 p.m.), representing each of the 168 hours of the week (1\_00 to 7\_23).
- ›  $\alpha_{D,H}$  is the coefficient to be multiplied by the heating degree days (HDD) to obtain the portion of the load attributable to heating.
- ›  $x^*$  is the heating degree days (HDD) for a balance point of 15 °C at the event time at which the baseline is assessed.
- ›  $\beta_{D,H}$  is the portion of the load that is not attributable to heating.

To ensure a close match between outdoor temperature and participant location, all participants were assigned to one of eight weather stations based on their postal code and zones associated to each weather station instead of using one weather dataset for all participants.

## Data Cleaning

The initial dataset included all participants (272) with Mysa thermostats. Among those, only 247 participants had AMI data available. The Evaluator only kept participants that did not have a participating EV charger (40 of the 247 participants had an EV charger) since the load from EV chargers created substantial noise in the dataset. In parallel, two participants with less than half the expected datapoints were excluded. Also, six participants were excluded as they had two premise addresses<sup>3</sup> and were therefore considered to have moved during the metering period, resulting in a total of 199 participants being included in the final analysis.

The Evaluator adjusted the initial 15-minute kW data to hourly data to be able to match them with hourly weather data. Hourly datapoints that did not include a full hour of data (four datapoints) were excluded. The Evaluator also excluded hourly datapoints that showed a load above 15 kW (0.3% of total datapoints) since they were considered outliers.

<sup>2</sup> Heating degree days were selected in lieu of outdoor temperature to better represent the heating load associated to each hour of the week. The heating degree days herein correspond to heating degree hours since they were calculated for each hour.

<sup>3</sup> Seven participants had two premise addresses, but one was already excluded because of their EV.

## Margin of Error

Once regression analyses were completed, the Evaluator ensured that all coefficients were significant (p-value < 0.05). The following equation was used to establish the margin of error on the **predicted load** for each hour (h).

$$Predicted\ kWh \pm E_{Predicted} = (\alpha_{D,H} \cdot x^* + \beta_{D,H}) \pm 1.64 \cdot RMSE_h \sqrt{\frac{1}{n_h} + \frac{(x^* - \bar{x}_h)^2}{n_h \sigma_h^2}}$$

Where:

- ›  $\beta_{D,H}$  is the regression intercept.
- ›  $\alpha_{D,H}$  is the regression slope.
- ›  $RMSE_h$  is the hourly model root mean square error.
- ›  $n_h$  is the number of observations.
- ›  $\bar{x}_h$  is the mean HDD.
- ›  $\sigma_h^2$  is the variance in HDD.
- ›  $x^*$  is the desired HDD at which evaluations are performed.

The actual load is the average of all participant loads at a given hour, and the margin of error is therefore obtained by multiplying the standard error of the average by the Student's t distribution variable ( $t_v$ ) as demonstrated in the following equation:

$$E_{Actual} = t_v \times Standard\ Error$$

Then, the predicted and actual load errors were propagated using the equation below to obtain the uncertainty on the calculated load reduction for each hour (h) of each event (EventX):

$$E_{Load\ Reduction, EventX, h} = \sqrt{E_{Predicted}^2 + E_{Actual}^2}$$

Finally, the error on the average load reduction per participant during events, which corresponds to the unitary available DR capacity, is calculated as:

$$E_{Unitary\ Savings} = \frac{\sqrt{\sum E_{LoadReduction, EventX, h}^2}}{n_{Events}}$$

## APPENDIX III

## APPENDIX VI

### BNI DR: Tracking Sheet Audit

This document presents the detailed results of the tracking sheet audit performed by the Evaluator, which was aimed at:

- › Verifying that all data fields required for the evaluation were included and filled out in the tracking sheet submitted by E1
- › Ensuring that tracked results were accurate by:
  - › Verifying that parameters used to calculate program results (new and available DR capacities at the generator) were consistent with previous evaluation results
  - › Validating that all calculation steps were performed consistently

Table 1 presents the corrected tracked new and available DR capacities. The slight difference is due to the Evaluator correcting the methodology used by E1 to determine average savings for some participants with events that should have been excluded.

**Table 1: 2024 BNI DR Corrected Tracked Available DR Capacity**

| Program Component Result    | Value Tracked by E1 |      | Corrected Tracked Value |      | Relative Difference |
|-----------------------------|---------------------|------|-------------------------|------|---------------------|
|                             | Value               | Unit | Value                   | Unit | Value               |
| New Available DR Capacity   | 5.553               | MW   | 5.702                   | MW   | 3%                  |
| Total Available DR Capacity | 7.917               | MW   | 8.067                   | MW   | 2%                  |

## APPENDIX VII

### BNI DR: Available DR Capacity Calculation Example

---

As per the definition agreed upon by E1 and NSP, available DR capacity is evaluated based on events called from December to February excluding weekends and holidays. Events called at any time during the day (morning or evening)<sup>4</sup> are included. Available DR capacity is evaluated on a per-participant basis based on the average demand reduction observed for each event that the participant was scheduled to participate in regardless of whether events are in the morning or evening. As per this definition, E1's total available DR capacity is the sum of each participant's available DR capacity.

As per the definition, only performances of participants for which the event was called are included in the available DR capacity calculation. If there is an event for which a given participant is not called on to participate, the participant is not included in the available capacity calculation, even though they contributed 0 kW in load reduction during this event. By averaging load reductions at the participant level first (as required by the available DR capacity definition) rather than averaging events, this will yield a higher average available DR capacity if some participants are not called on in all events. In 2024, there were two instances of participants not being called for a given event: (1) For one morning event, only participants best suited to respond in the morning were called to participate and (2). For one day, both a morning event and evening event were called and participants participated in only one of the events based on which event is best suited for the participant. All participants are categorized by E1 as either being better suited to morning or to evening events, and for each event, E1 can decide to only call participants that are better suited to that time, or to call all participants to take part in that event.

To illustrate how available DR capacity is calculated, the Evaluator prepared the example presented in Table 1. The example was developed using only five participants and five events to better visualize the impact of events not called for all participants. Numbers provided are for illustrative purposes only and are not based on actual participant data. In this example, Event 3 was only called for morning-suited participants, while Event 5 included morning (Event 5.1) and evening (Event 5.2) event windows for which each participant took part in only the morning or evening window, based on the type of event for which they were best suited.

---

<sup>4</sup> Available DR capacity for morning peak events includes all events prior to 12 p.m. and available DR capacity for evening peak events includes all events between 12 p.m. and 12 a.m. However, the events are typically called around 7 a.m. and 5 p.m.

**Table 1: Available DR Capacity Calculation Example**

| Event Number                     | Event Period | Type of Participants for Which the Event Was Called | Load Reduction per Participant per Event (kW) |                |                |                |                | Sum of Load Reduction per Event (kW) |
|----------------------------------|--------------|-----------------------------------------------------|-----------------------------------------------|----------------|----------------|----------------|----------------|--------------------------------------|
|                                  |              |                                                     | Part. #1                                      | Part. #2       | Part. #3       | Part. #4       | Part. #5       |                                      |

| 1                                | Evening      | All                                                 | 690                                           | 470            | 530            | 660            | 380            | 2,730                                |
| 2                                | Morning      | All                                                 | 330                                           | 540            | 610            | 290            | 920            | 2,690                                |
| 3                                | Morning      | Morning-suited                                      |                                               |                | 520            | 910            |                | 1,430                                |
| 4                                | Morning      | All                                                 | 640                                           | 850            | 650            | 380            | 170            | 2,690                                |
| 5.1                              | Morning      | Morning-suited                                      |                                               |                | 100            | 570            |                | 670                                  |
| 5.2                              | Evening      | Evening-suited                                      | 260                                           | 260            |                |                | 980            | 1,500                                |
| Average Load Reduction per Event |              |                                                     |                                               |                |                |                |                | 1,952                                |
| Average Available DR Capacity    |              |                                                     | 480                                           | 530            | 482            | 562            | 613            | 2,667                                |

In Table 1, the available DR capacity presented in the bottom right corner (2,667 kW) is the sum of the average available DR capacity of each participant (bottom line), which corresponds to E1's definition of available DR capacity. Therefore, E1 will sum the participant average instead of the event average when reporting on average available DR capacity. As aforementioned, this value differs from the average of the load reduction per event (last column), which is 1,952 kW.

If all events had been called for all participants, the available DR capacity would be identical to the average load reduction per event. The magnitude of the difference between the two results will increase if a higher proportion of events are called only for a portion of participants. As noted above, out of the 10 events called during the 2023-2024 winter, E1 called one morning event only for morning-suited participants, and one double-event day for which participants took part only in the morning or the evening part of the event. Moving forward, E1 intends to call events for all participants on days with only one event and aims to call on morning and evening-suited participants separately on days with more than one event.

## APPENDIX VIII

# BNI DR: Baseline Considerations

---

### General Guidelines

The general guidelines that serve as the de facto assumptions for any DR M&V are presented below:

- › High 6 of 10 baseline
- › Additive adjustment
- › Adjustment lookback window spans two hours
- › Adjustment lookback window starts three hours before the event begins, i.e. the first hour before an event not included in adjustments
- › Adjustments are symmetric, i.e. curtailment can be adjusted up or down
- › Holidays and Weekends are excluded from the baseline
- › Adjustments are capped at  $\pm 20\%$

### Additive Adjustment

Additive adjustments involve a fixed kW adjustment across all event time intervals. It's suitable for situations where there's a known, constant change in the load that is not proportional to the baseline, like the addition or removal of a piece of equipment with a constant load.

---

*Example: an industrial process is running on the day of the event which does not normally run and is not present in the baseline days. Or, it was a slow day and a process was shut down that is normally operational on baseline days.*

---

|            |                |
|------------|----------------|
| Article I. | Business Rules |
|------------|----------------|

- 1) Always use additive adjustments unless the curtailed load is temperature-sensitive.

### Scalar Adjustment

Scalar adjustment are a percentage multiplier applied across all event time intervals. It's appropriate when the baseline needs to be adjusted proportionally due to predictable changes that affect the entire load profile, such as consistent changes in operational hours or production levels.

---

*Example: the load being curtailed is primarily HVAC and is sensitive to outdoor temperature. It is a particularly cold day, and load was higher than on baseline days.*

---

## Business Rules

- 2) Only use a scaler adjustment if the curtailed load is known to be sensitive to changes in temperature.

### Lookback window

Following are considerations when making adjustments to the lookback window:

#### Define Objectives

Determine what the lookback window should achieve, such as reflecting typical usage patterns, operational hours, or accounting for seasonal variations.

#### Analyze Historical Data

Look at historical consumption data to identify normal usage patterns and any anomalies.

#### Consider Variability

Account for variability in operations, weather conditions, and other factors that could affect energy usage.

#### Select Duration

Choose a duration that is long enough to provide a representative sample of usage but not so long that it includes outdated values.

#### Set Timing

Align the timing of the lookback window with the DR event's expected impact on consumption.

#### Test and Validate

Test the lookback window against past DR events to validate its effectiveness.

#### Review and Adjust

Regularly review the lookback window's performance and make adjustments as necessary.

#### Document and Communicate

Clearly document the methodology and communicate it to all stakeholders.

## Business rules

- 3) If the lookback window is observing an abnormal condition such as a building opening or closing earlier than normal, consider whether this point in time is a valid point of comparison.

Consider the example below. The facility shut down from ~10 AM to 4 PM. The facility then resumed normal operation. A DR event was scheduled for 5 PM, one hour before the facility normally closes. The adjustment window “sees” the abnormal shut down and creates a significant, negative additive adjustment. Because the facility resumed normal operation, the temporary one-off shut down before the event should not be used to calculate an adjustment.

Figure 1: Business rule 3 example. Solid blue line load throughout the day; the dotted red line is the baseline before adjustment; the green shaded area is curtailment after scaler adjustment is applied; the blue shaded area is curtailment after additive adjustment is applied; the solid yellow line is the demand during the event, it always overlaps 100% with the solid blue line, and is only shown to isolate the load observed during the DR event.

## Adjustment Cap

Following are considerations when making adjustments to the adjustment cap:

### Reflect Actual Conditions

The cap should reflect the actual conditions and operational changes that could reasonably affect the DR event day's load.

### Prevent Overcompensation

It should prevent overcompensation for reductions that would have occurred without the DR event.

### Based on Historical Data

The cap can be based on a percentage of historical adjustments observed during similar DR events or established through statistical analysis.

### Consider Program Goals

The cap should align with the overall goals of the DR program, whether it's peak shaving, load shifting, or emergency response.

### Ensure Fairness

It should be fair and not disadvantage any participants, regardless of their size or consumption patterns.

### Be Transparent

The methodology for establishing the cap should be transparent and well-documented to maintain stakeholder trust.

### Allow for Exceptions

There should be provisions for exceptional circumstances where the standard cap may not be appropriate, with clear guidelines on how these exceptions are handled.

### Regular Review and Update

The cap should be reviewed and updated regularly to ensure it remains relevant and effective as grid conditions and participant behaviors change.

## Business Rules

- 4) If the default 20% adjustment cap does not accurately encompass the total curtailment for the specified event day, i.e. a very abnormal day was confirmed by the business, consider allowing for an exception on the default adjustment cap.

## Symmetry

Adjustments are applied symmetrically, i.e. results could go up or down. The symmetric approach considers that day-of conditions can have a real impact on customer demand in both directions and therefore it can be argued that symmetric adjustments maximize the accuracy of a baseline calculation. The  $\pm 20\%$  cap stated in the General Guidelines above will help reduce any negative consequences of a downward adjustment.

It is also worthwhile to consider moving the adjustment window to earlier than 2 hours before the event, or even moving it to after the event, to yield a better adjustment factor.

### Business Rules

- 5) If the lookback window provides an abnormal positive or negative adjustment factor, the event should be flagged and considered with more detailed, as a new adjustment period may need to be selected, including the hours proceeding the event, for a more accurate depiction of the customer's load. If the lookback window is observing an abnormal condition such as a building opening or closing earlier than normal, consider whether this point in time is a valid point of comparison.

## Exclusion rules

Exclusion rules – Some days are excluded from consideration such as holidays, previous DR event days, weekends, thresholds and scheduled shutdowns (as these are not representative of “normal” operation).

---

*Example: A facility was closed for a week due to renovations. During this time, Energy usage was abnormally low and is not representative of typical operation; these days should be excluded from the baseline calculation.*

---

### Business Rules

- 6) If there are known irregularities in customer usage that are not representative of typical operation, such days should be excluded from the baseline calculation. Rationale for exclusion must be documented in CIS for that customer.

## APPENDIX IX

### BNI DR: Project Review Protocol

Presented below is the template used by the Evaluator to review projects to determine evaluated savings.

|                                                                     |                |                |                |                |                |                |                |                |                |                 |         |

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Accuracy</b>                           | Reflects the proximity of measurements to the true value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Adjustment ratio</b>                   | The ratio of evaluated results to tracked results. This ratio expresses the adjustment made to tracked savings or other tracked values such as effective useful life.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Available demand response capacity</b> | The capacity which is available to NSP to reduce system peak demand. This capacity is calculated based on the first two hours of all events called between December and February, excluding weekends and holidays. If an event is shorter than two hours, only the first hour is used to measure the available DR capacity. Available DR capacity is evaluated on a per-participant basis, based on the average demand reduction observed for each event that the participant was scheduled to participate in. E1's total available DR capacity is the sum of each participant's available DR capacity. |
| <b>Baseline</b>                           | To determine gross savings, a baseline (or base case) is established providing detailed information about the reference (e.g. pre-existing or standard) measure or equipment chosen to be compared with the efficient measure or equipment. For the reference measure or equipment, the baseline may include such information as the hours of operation, wattage, and base consumption.                                                                                                                                                                                                                 |
| <b>Bias</b>                               | Systematic deviations of measurements from the true value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Billing calibration</b>                | An activity that consists of adjusting the expected energy savings based on the relative difference between the results of energy simulations and the actual energy consumption of a building or system.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Confidence interval</b>                | The estimated range of values that is likely to include unknown population parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Demand response</b>                    | Demand response measures generate savings in the form of available capacity or load reduction in response to events called by the electric utility (Nova Scotia Power) to reduce the load at strategic moments. These events can be called at any time and for any duration, although they are usually called for two to four hours during peak periods.                                                                                                                                                                                                                                                |
| <b>Displaced wattage</b>                  | The displaced wattage is defined as the difference between the wattage values of the baseline equipment or product and the efficient equipment or product.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>EnerGuide rating</b>                   | An EnerGuide (official brand of Natural Resources Canada) rating is a standard measure of home energy performance. It is a measure of the efficiency of the building only and does not take into account occupant behaviour. It shows how energy efficient a home is through modelled home heat losses based on several factors including building envelope characteristics, heated volume, heating systems, and air leakage.                                                                                                                                                                           |
| <b>Effective useful life</b>              | The period a measure is expected to be in service and provide both energy and peak demand savings. This value combines equipment life and measure persistence, which includes factors such as business turnover or early retirement.                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Equipment life</b>                     | The number of years installed equipment will operate before it fails.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                                         |                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Equivalent CO2</b>                   | A unit of measurement indicating the amount of carbon dioxide to which various kinds of emitted greenhouse gases are equivalent in terms of warming effects. In this report, gas global-warming potential is estimated over a timescale of 100 years.                                                                |
| <b>Equivalent effective useful life</b> | The number of years by which the first-year savings estimate is multiplied to obtain lifetime energy savings. This value takes into account variations in annual energy savings throughout the effective useful life due to increased baselines.                                                                     |
| <b>Evaluated savings</b>                | Gross and net energy or peak demand savings calculated by the Evaluator using the parameters (unitary savings values, installation rates, interactive effects, net-to-gross ratios, etc.) validated or measured during the evaluation process. Unless otherwise specified, evaluated savings are first-year savings. |
| <b>Evaluation plan</b>                  | The evaluation plan summarizes the program description, objectives, base cases, documentation, evaluation methodology, budget, and schedule.                                                                                                                                                                         |
| <b>First-year savings</b>               | The first full year of energy or peak demand savings generated by an energy efficiency measure.                                                                                                                                                                                                                      |
| <b>Free-ridership</b>                   | Percentage of gross savings attributable to participants who would have implemented the same or similar energy efficiency measures, with no change in timing, in the absence of the program.                                                                                                                         |
| <b>Gross savings</b>                    | Change in energy consumption and/or demand that results directly from program-related actions taken by participants in an efficiency program regardless of why they participated.                                                                                                                                    |
| <b>Induced consumption</b>              | Energy consumption of appliances that would have been unplugged and not replaced by participants in the absence of the program.                                                                                                                                                                                      |
| <b>Interactive effects</b>              | Effects on the energy consumption of other systems in a building (such as heating and cooling) due to the installation of an energy-efficiency measure.                                                                                                                                                              |
| <b>In-service rate</b>                  | The proportion of incentivized products that are installed and operating. This rate is usually applied to programs through which rebates are offered in-store and products are likely to be stored for a certain period before being installed, such as LED lamps.                                                   |
| <b>Installation rate</b>                | The proportion of incentivized products reported as installed and that remain installed and operating at the time of evaluation. This rate is usually applied to direct install or mail-in rebate programs through which measures are expected to be installed immediately at the time of participation.             |
| <b>Lifetime energy savings</b>          | The energy savings that occur over the lifetime of an energy efficiency measure. Lifetime energy savings account for a measure's effective useful life and any increase in the baseline efficiency level (which reduces attributable annual savings) over its lifetime.                                              |
| <b>Line loss factor</b>                 | The multiplier to convert savings at the customer meter to savings at the utility generator. It accounts for the electrical losses of the transmission and distribution system.                                                                                                                                      |
| <b>Margin of error</b>                  | The amount of random sampling error.                                                                                                                                                                                                                                                                                 |

|                                 |                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Market effects</b>           | The impact of a program on the market (in terms of increased product availability, practices, and prices) that extends beyond changing program participant behaviours. This includes spillover among non-participants.                                                                                                                       |
| <b>Net savings</b>              | Energy or peak demand savings that can be reliably attributed to a program. This includes effects such as free-ridership and spillover that negatively or positively affect the savings attributable to a program.                                                                                                                           |
| <b>Net-to-gross ratio</b>       | The ratio of net energy savings to gross energy savings.                                                                                                                                                                                                                                                                                     |
| <b>Non-sampling error</b>       | Errors arising during all survey activities other than sampling. Non-sampling errors tend to lead to bias in measurements and are very difficult to quantify.                                                                                                                                                                                |
| <b>Peak coincidence factor</b>  | The percentage of measure demand savings that coincide in time with the annual peak demand of the entire electricity system.                                                                                                                                                                                                                 |
| <b>Peak demand savings</b>      | The demand savings that coincide in time with the expected annual peak demand period of the entire electricity system. For industrial participants on an interruptible rate, peak demand savings may include savings on non-firm loads, i.e. loads that may be interrupted when Nova Scotia Power's 10-minute reserve is low.                |
| <b>Precision</b>                | The extent to which repeated measurements agree with one another.                                                                                                                                                                                                                                                                            |
| <b>Random sampling error</b>    | An error in measurement because measurements are taken from a subset of the population and not the entire population.                                                                                                                                                                                                                        |
| <b>Realization rate</b>         | The ratio of evaluated savings to tracked savings.                                                                                                                                                                                                                                                                                           |
| <b>Sample size</b>              | The number of observations or replicates included in a statistical sample.                                                                                                                                                                                                                                                                   |
| <b>Secondary market impacts</b> | Energy consumption of appliances that would have been transferred to the secondary market if said appliances had not been retired.                                                                                                                                                                                                           |
| <b>Spillover</b>                | Savings attributable to participants who implement the energy efficiency measure(s) introduced by a program after participating in it once, without participating in the program a second time.                                                                                                                                              |
| <b>Tracked savings</b>          | Gross and net savings calculated based on various parameters such as number of participants or units installed or sold, unitary savings values, installation rates, interactive effects, and net-to-gross ratios. Those parameters, except the number of participants or units installed or sold, are obtained from the previous evaluation. |
| <b>Unitary savings</b>          | Energy or peak demand savings established on a unitary basis. A unit can either be a product (e.g. an 8 W LED lamp), a capacity (e.g. one-tonne capacity of an air-source heat pump), or a participant (e.g. one participant taking part in a behaviour-based program).                                                                      |

| <b>Residential Measure Assessment Change Log .....</b>      | <b>xxiii</b> |
| <b>Introduction.....</b>                                    | <b>1</b>     |
| <b>1 Residential Measure Assessment Scope.....</b>          | <b>4</b>     |
| <b>2 Residential Measure Gross Savings Parameters .....</b> | <b>7</b>     |
| 2.1 Lighting.....                                           | 7            |
| 2.1.1 Interactive Effects .....                             | 7            |
| 2.1.2 Peak Demand Savings Factors.....                      | 11           |
| 2.1.3 Lighting Measures.....                                | 12           |
| (1) LED Lamps .....                                         | 12           |
| (2) LED Fixtures .....                                      | 18           |
| (3) Dimmer Switches .....                                   | 21           |
| (4) Motion Sensors .....                                    | 23           |
| (5) LED Nightlights .....                                   | 27           |
| (6) Solar Fixtures.....                                     | 28           |
| 2.2 Water Heating .....                                     | 31           |
| 2.2.1 Interactive Effects .....                             | 31           |
| 2.2.2 Peak Demand Savings Factors.....                      | 33           |
| 2.2.3 Water Heating Measures .....                          | 34           |
| (1) Drain Water Heat Recovery .....                         | 34           |
| (2) Solar Domestic Hot Water.....                           | 36           |
| (3) Heat Pump Water Heaters .....                           | 37           |
| (4) Low-flow Showerheads .....                              | 40           |
| (5) Faucet Aerators .....                                   | 44           |
| (6) Thermostatic Shower Valves.....                         | 47           |
| (7) Pipe Insulation .....                                   | 49           |
| (8) Hot Water Tank Wraps.....                               | 50           |
| 2.3 Space Heating.....                                      | 53           |
| 2.3.1 Interactive Effects .....                             | 53           |
| 2.3.2 Peak Demand Savings Factors.....                      | 54           |
| 2.3.3 Space Heating Measures.....                           | 55           |
| (1) Mini-split Heat Pumps .....                             | 55           |
| (2) Central Air-source Heat Pumps.....                      | 57           |
| (3) Ground-source Heat Pumps.....                           | 59           |

|       |                                                                                  |     |

| Update      | 2.4.3 (2) Refrigerator Replacements and (3) Freezer Replacements                                                                                          | Measures are now listed under HomeWarming and MHEEP in place of ARet                                                                                                                                                                                                                                               | 2024-03-12 |
| Update      | 2.6.3 (4) Domestic Water Heater Load Controls                                                                                                             | Updated unitary savings values                                                                                                                                                                                                                                                                                     | 2024-03-12 |
| Update      | 3 Effective Useful Life                                                                                                                                   | Added AMH EUL values to the lists. Added MHEEP to the program for which a few EUL values were applicable                                                                                                                                                                                                           | 2024-03-12 |
| Update      | 2.3.3 (7) Air Sealing Kits                                                                                                                                | Name changed to Air Sealing Products, and savings are now presented per product rather than by kit                                                                                                                                                                                                                 | 2024-03-12 |
| Update      | 2.1.1 Interactive Effects                                                                                                                                 | Updated heat pump Coefficient of performance (COP) value. Updated space heating and cooling system distribution for Instant Savings                                                                                                                                                                                | 2025-03-19 |
| Update      | 2.1.3(1) LED Lamps                                                                                                                                        | Updated HOU values. Updated EUL and equivalent EUL values to account for LED lamps becoming the baseline in 2025. Removed mention of mail-out pilot kit for EPI. Unitary savings values updated with final Instant Savings 2024 TS data. Updated EPI installation rate according to 2024 EPI on-site visit results | 2025-03-19 |
| Update      | 2.1.3(2) LED Fixtures                                                                                                                                     | Updated HOU values for recessed downlight fixtures and LED fixtures. Updated EUL and equivalent EUL values to account for LED lamps becoming the baseline in 2025. HOU values for LED fixtures with motion sensors and unitary savings values updated with final Instant Savings 2024 TS data                      | 2025-03-19 |
| Update      | 2.1.3(3) Dimmer Switches                                                                                                                                  | Updated HOU value and controlled wattage. Added as an EPI measure                                                                                                                                                                                                                                                  | 2025-03-19 |
| Update      | 2.1.3(4) Motion Sensors                                                                                                                                   | Updated outdoor representative lamp mix. Added as an EPI measure (indoor and outdoor only)                                                                                                                                                                                                                         | 2025-03-19 |
| Update      | 2.1.3(5) LED Nightlights                                                                                                                                  | Updated EUL and equivalent EUL values to account for LED lamps becoming the baseline in 2025. Removed mention mail-out pilot kit. Updated installation rate according to 2024 EPI on-site visit results                                                                                                            | 2025-03-19 |
| Update      | 2.1.3(6) Solar Fixtures                                                                                                                                   | Updated EUL value and outdoor representative lamp mix. Added as an EPI measure                                                                                                                                                                                                                                     | 2025-03-19 |
| Update      | 2.2.1 Interactive Effects                                                                                                                                 | Updated heat pump COP value based on HSPF2                                                                                                                                                                                                                                                                         | 2025-03-19 |

| Change Type | Section                                                            | Description                                                                                                                                                                                                                                                                                                                  | Date       |
|-------------|--------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| Update      | 2.2.3(3) Heat Pump Water Heaters                                   | Updated space heating system distribution for IS. Updated share of electric water heaters for IS with EPI 2022-2023 TS data. Updated EUL value                                                                                                                                                                               | 2025-03-19 |
| Update      | 2.2.3(4) Low-flow Showerheads                                      | Removed mention of mail-out pilot kit. Updated installation rate and number of showerheads per household according to 2024 EPI on-site visit results. Updated electric water heating efficiency                                                                                                                              | 2025-03-19 |
| Update      | 2.2.3(5) Faucet Aerators                                           | Removed mention of mail-out pilot kit. Updated installation rate and number of faucets per household according to 2024 EPI on-site visit results. Updated electric water heating efficiency                                                                                                                                  | 2025-03-19 |
| Update      | 2.2.3(6) Thermostatic Shower Valves                                | Updated available flow rates to only include 2.5 gpm since other flow rates were discontinued. Updated installation rate and number of showerheads per household according to 2024 EPI on-site visit results. Updated electric water heating efficiency                                                                      | 2025-03-19 |
| Update      | 2.2.3(7) Pipe Insulation                                           | Removed mention of mail-out pilot kit                                                                                                                                                                                                                                                                                        | 2025-03-19 |
| Update      | 2.2.3(8) Hot Water Tank                                            | Updated installation rate according to 2024 EPI on-site visit results. Updated electric water heating efficiency                                                                                                                                                                                                             | 2025-03-19 |
| Update      | 2.3.3(1) Mini-split Heat Pumps                                     | Unitary savings values to be updated with GH and HEA billing analyses                                                                                                                                                                                                                                                        | 2025-03-19 |
| Update      | 2.3.3(3) Ground-source Heat Pumps                                  | Updated efficiencies to HSPF2 and SEER2. Updated FLH based on HEA heating load                                                                                                                                                                                                                                               | 2025-03-19 |
| Update      | 2.3.3(4) Wood and Pellet Stoves/Fireplace Inserts                  | Updated heat pump COP based on HSPF2. Unitary savings values to be updated with GH and HEA billing analyses                                                                                                                                                                                                                  | 2025-03-19 |
| Update      | 2.3.3(7) Air Sealing Products                                      | Updated unitary savings values following 2023 change in delivery in which products were delivered individually and not in a kit. Updated heat pump COP based on HSPF2. Removed mention of mail-out pilot kit. Updated installation rate according to 2024 EPI on-site visit results                                          | 2025-03-19 |
| Update      | 2.3.3(8) Window Film Kits                                          | Updated heat pump COP value based on HSPF2. Updated installation rate according to 2024 EPI on-site visit results. Updated unitary energy savings and unitary peak demand savings values to correct rounding error                                                                                                           | 2025-03-19 |
| Update      | 2.3.3(9) Programmable Thermostats                                  | Updated unitary savings value in IS to reflect an electronic thermostat baseline. Updated algorithm to provide two unitary savings values in MHEEP with an electronic thermostat baseline and an analog thermostat baseline                                                                                                  | 2025-03-19 |
| Update      | 2.3.3(10) Smart Thermostats for Electrical Heating Systems         | Updated average heating energy with HEA 2021-2023 TS data. Updated heat pump COP based on HSPF2. Updated installation rate according to 2024 EPI on-site visit results. Applied reduction to apartment unitary energy savings value to account for differences between single-family home and apartment heating loads in EPI | 2025-03-19 |
| New Measure | 2.3.3(11) Advanced Learning Thermostat for Central Heating Systems | Added measure                                                                                                                                                                                                                                                                                                                | 2025-03-19 |
| Removal     | 2.4.3(1) Clotheslines and Outdoor                                  | Removed product in EPI as it is no longer a                                                                                                                                                                                                                                                                                  | 2025-03-19 |

| Change Type | Section                                                                               | Description                                                                                                                                                                                                                                                                                                         | Date       |

| Update      | 2.4.3(2) Refrigerator Retirements/Replacements                                        | Updated annual consumption per size for appliances after 2002 for ARet. Updated product characteristics based on 2021-2023 average for ASFH and MHEEP through ARet. Proportion of refrigerators updated with final ARet 2024 TS                                                                                     | 2025-03-19 |
| Update      | 2.4.3(3) Freezer Retirements/Replacements                                             | Updated annual consumption per size for appliances after 2002 for ARet. Updated product characteristics based on 2021-2023 average for ASFH and MHEEP through ARet. Proportion of freezers updated with final ARet 2024 TS                                                                                          | 2025-03-19 |
| Update      | 2.4.3(4) Room Air Conditioner Retirements                                             | Updated Energy efficiency ratio (EER). Updated average capacity based on 2021-2023 average                                                                                                                                                                                                                          | 2025-03-19 |
| Update      | 2.4.3(5) Dehumidifier Replacements or Retirements/ENERGY STAR Certified Dehumidifiers | Energy factor of efficient dehumidifier updated with final 2024 TS for ASFH and MHEEP through ARet                                                                                                                                                                                                                  | 2025-03-19 |
| Update      | 2.4.3(6) ENERGY STAR Certified Clothes Dryers                                         | Updated baseline unit combined energy. New unit combined energy factor updated with final Instant Savings 2024 TS data                                                                                                                                                                                              | 2025-03-19 |
| Update      | 2.4.3(7) Efficient Clothes Washers                                                    | Updated calculation of electric water heating percentage to exclude internal heaters. Updated DHW tank distribution with EPI 2022-2023 TS data. Integrated Modified Energy Factor updated with final Instant Savings 2024 TS data                                                                                   | 2025-03-19 |
| Update      | 2.4.3(8) Efficient Washer-Dryer Combination Units                                     | Updated baseline unit combined energy factor. Updated calculation of electric water heating percentage to exclude internal heaters. Updated DHW tank distribution with EPI 2022-2023 TS data. New unit combined energy factor and Integrated Modified Energy Factor updated with final Instant Savings 2024 TS data | 2025-03-19 |
| Update      | 2.4.3(10) ENERGY STAR Certified Dishwashers                                           | Updated baseline unit consumption. Updated percentage of electric DHW savings. Efficient unit consumption updated with final Instant Savings 2024 TS data                                                                                                                                                           | 2025-03-19 |
| New Measure | 2.4.3(11) Humidity Sensors for Bathroom Exhaust Fans                                  | Added measure                                                                                                                                                                                                                                                                                                       | 2025-03-19 |
| Update      | 2.5.3(1) Smart Power Controllers for Audiovisual Equipment                            | Updated unitary savings value and installation rate for IS. Updated EPI installation rate according to 2024 EPI on-site visit results                                                                                                                                                                               | 2025-03-19 |
| Update      | 2.5.3(2) Power Bars with Integrated Timers                                            | Updated idle lighting wattage                                                                                                                                                                                                                                                                                       | 2025-03-19 |
| New Measure | 2.7.3(1) Solar Photovoltaic Systems                                                   | Measure added (already existed, just not in the MA). Updated EUL                                                                                                                                                                                                                                                    | 2025-03-19 |
| Update      | 2.3.3.(1) Mini-split Heat Pumps                                                       | Updated unitary savings according to 2024 billing analysis                                                                                                                                                                                                                                                          | 2025-03-19 |
| Update      | 2.3.3(4) Wood and Pellet Stoves/Fireplace Inserts                                     | Updated unitary savings according to 2024 billing analysis                                                                                                                                                                                                                                                          | 2025-03-19 |

# INTRODUCTION

---

The 2024-2025 DSM Measure Assessment (MA) presents the results of an in-depth review of all parameters necessary to calculate the annual and lifetime gross energy and peak demand savings of most prescriptive measures and some semi-prescriptive measures offered through the EfficiencyOne (E1) Demand-side management (DSM) program portfolio. The 2024 edition presents the results of an in-depth review of all residential measures and of the top-10 commercial measures.

This document is focused only on gross electric energy and peak demand savings. Appendix V presents the approach reviewed by the Evaluator in 2024 to determine net-to-gross ratios and, ultimately, net savings.

## Purpose

The objectives of this document are to:

- › Ensure consistency in gross savings values throughout the three-year DSM cycle and thus improve E1's ability to define and track targets for energy and peak demand savings
- › Consolidate E1's gross savings values into a single reference document that can easily be referred to by program staff and useful to populate E1's internal e-Technical Reference Manual (e-TRM)

## Use and Application

For the evaluations conducted during the last two years of the 2023-2025 demand-side management (DSM) cycle, the Evaluator will refer to the values presented in the 2024-2025 DSM MA.

The MA includes the following elements:

- › Interactive effects
- › Peak demand-to-energy ratios and peak coincidence factors
- › Installation and in-service rates
- › Unitary savings

In addition to the elements listed above, the MA includes effective useful life (EUL) values for all measures offered in E1's program portfolio. Also, the savings for some programs targeting demand response (DR) are called available DR capacity. DR measures differ from demand reduction measures because they only generate savings when events are called while demand reduction measures generate peak demand savings throughout the peak demand period.

## Development and Review Process

Savings are established using one or more of the following approaches: Literature reviews of TRMs; metering studies and evaluation reports; engineering calculations; adjustments based on data collected through participant surveys or site visits; and secondary research about household/facility characteristics such as types of heating and cooling systems.

The Evaluator established guidelines to determine how average parameters are calculated from tracking sheet data. For Instant Savings, the Evaluator used all 2024 data to establish product characteristic averages, given the rapid changes from year to year in this program. For all other parameters taken from tracking sheets (e.g. number of people per household, heating loads, equipment capacity), the Evaluator used an average value over the last three complete years available, namely 2021 to 2023. Using an average value over three years that is updated once every DSM cycle takes into consideration trends in parameters while limiting the impact of yearly variations. An exception to this rule may be made if there is a clear increase or decrease of the parameter year over year, which would make the 2023 value the most relevant one for future years – if an exception is made, it will be clearly noted. In some cases, parameters were not updated because they are no longer available in the tracking sheet; footnotes indicate where that is the case.

The parameters used in this 2024 edition of the MA will be valid throughout the DSM cycle except for the following parameters that will be updated annually in the MA:

- › LED lamps and fixtures for Instant Savings
  - › Baseline and efficient wattages
- › Major appliances for Instant Savings
  - › Baseline and efficient wattages, sizes and performance metrics
- › Freezer and refrigerator retirements<sup>1</sup>
  - › Proportion of units per manufacture-year class
  - › Average unit size

The parameters listed above have been updated as part of this edition.

Other parameters will also be updated in 2025 based on either applicable comprehensive evaluation results or changes to program offerings or delivery.

If new measures are introduced to the portfolio in a given year, they are reviewed as part of that year's evaluation, and the Evaluator updates the 2024-2025 MA accordingly. In the 2024 evaluation, the following measures were added: advanced learning thermostats for central heating systems, humidity sensor for bathroom exhaust fan, solar photovoltaic systems (residential), light-emitting diode (LED) roadway lighting, horticultural lighting, smart thermostats for electric baseboards in commercial facilities, solar photovoltaic systems (commercial). In addition, all measures from E1's commercial CIRx Screening Tool have been integrated to the MA.

## Savings Calculations Equations

The savings calculations are based on the equations outlined below.

### Electrical Energy Savings

The following equation is used to calculate electrical energy savings.

$$\begin{aligned} \text{Electrical Energy Savings (kWh)} \\ &= \text{Unitary Energy Savings (kWh)} \times (1 \\ &+ \text{Interactive Effects Factor for Energy Savings (\%)}) \times \text{"Installation Rate" or "In} \\ &- \text{service Rate" (\%)} \end{aligned}$$

---

<sup>1</sup> The average retired appliance efficiency levels and sizes are likely to evolve overtime as the year of manufacturing of these retired appliances becomes more recent.

## Peak Demand Savings

Peak demand savings correspond to the demand savings that coincide in time with the peak demand of the electricity system. The projected electricity peak demand period in Nova Scotia is between 5 p.m. and 7 p.m. from December to February on non-holiday weekdays.

The following equation is used to calculate peak demand savings.

$$\begin{aligned} \text{Peak Demand Savings (W)} &= \text{Unitary Peak Demand Savings (W)} \times (1 \\ &+ \text{Interactive Effects Factor for Peak Demand Savings (\%)}) \times \text{"Installation Rate " or " In} \\ &- \text{service Rate" (\%)} \end{aligned}$$

## Available Demand Response Capacity

Available DR capacity differs from peak demand savings since the former considers the potential load reduction that was made available instead of the actual load reduction that coincided with the actual utility peak. This distinction was made since E1 does not control the calling of events and thus does not control how well the resources made available are used to reduce peak demand. Available DR capacity is calculated based on the following assumptions:

- › Capacity is evaluated based on events called from December to February excluding weekends and holidays. Events called at any time during the day (morning or evening) can be included.
- › Available demand response capacity is measured over the first two hours of a DR event.
- › If an event is longer than two hours, only the first two hours are used to measure capacity.
- › If an event is shorter than two hours, only the first hour is used to measure available capacity.
- › Available DR capacity is evaluated on a per-participant basis based on the average demand reduction observed for each event in which the participant was scheduled to participate.
- › E1's total available DR capacity is the sum of each participant's available DR capacity.

The following equation is used to calculate available DR capacity.

$$\begin{aligned} \text{Available DR Capacity (W)} &= \text{Unitary Available DR Capacity (W)} \times (1 \\ &+ \text{Interactive Effects Factor for Peak Demand Savings (\%)}) \times \text{"Installation Rate " or " In} \\ &- \text{service Rate" (\%)} \end{aligned}$$

## Lifetime Energy Savings

Lifetime energy savings correspond to the savings that occur over the lifetime of the measures installed. The following equation is used to calculate lifetime energy savings.

$$\text{Lifetime Energy Savings (kWh)} = \text{Electrical Energy Savings (kWh)} \times \text{Effective Useful Life (years)}$$

# 1 Residential Measure Assessment Scope

Table 2 below lists the residential measures and associated programs included in the 2024-2025 DSM MA. The MA includes all necessary parameters and calculations to obtain gross energy and peak demand savings for all portfolio prescriptive and semi-prescriptive measures. In addition, effective useful life values are included for all prescriptive, semi-prescriptive, and custom measures.

For reference, savings calculations for prescriptive measures use fixed assumptions for all participants. The savings are identical for all units installed and represent the average savings for all units. Conversely, savings calculations for custom measures use inputs that are specific to each unit installed and thus represent the actual savings for each unit. Semi-prescriptive measures use a mix of two previous approaches by using unit-specific inputs as well as certain non-specific inputs to determine savings.

**Table 2: Included Residential Measures**

| Measure                       | Program Component |
|-------------------------------|-------------------|
| <b>Lighting</b>               |                   |
| LED Lamps                     | EPI               |
|                               | Instant Savings   |
| LED Fixtures                  | Instant Savings   |
| Dimmer Switches               | Instant Savings   |
| Motion Sensors                | Instant Savings   |
| LED Nightlights               | EPI               |
| Solar Fixtures                | Instant Savings   |
| <b>Water Heating</b>          |                   |
| Drain Water Heat Recovery     | MHEEP             |
| Solar Domestic Hot Water      | Green Heat        |
| Heat Pump Water Heaters       | HEA               |
|                               | MHEEP             |
|                               | Instant Savings   |
| Low-flow Showerheads          | EPI               |
| Faucet Aerators               | EPI               |
| Thermostatic Shower Valves    | EPI               |
| Pipe Insulation               | EPI               |
| Hot Water Tank Wraps          | EPI               |
| <b>Space Heating</b>          |                   |
| Mini-split Heat Pumps         | Green Heat        |
|                               | HEA               |
|                               | MHEEP             |
| Central Air-source Heat Pumps | Green Heat        |
|                               | HEA               |
| Ground-source Heat Pumps      | Green Heat        |

| Measure                                                                      | Program Component |
|------------------------------------------------------------------------------|-------------------|
|                                                                              | HEA               |
| Wood and Pellet Stove/Fireplace Inserts                                      | HEA               |
|                                                                              | Green Heat        |
| Wood and Pellet Boilers and Furnaces                                         | HEA               |
|                                                                              | Green Heat        |
| Solar Air Heating                                                            | Green Heat        |
| Air Sealing Products                                                         | EPI               |
| Window Film Kits                                                             | EPI               |
| Programmable Thermostats                                                     | Instant Savings   |
|                                                                              | MHEEP             |
| Smart Thermostats for Electric Heating Systems                               | Instant Savings   |
|                                                                              | EPI               |
|                                                                              | MHEEP             |

## 2 Residential Measure Gross Savings Parameters

The following sections outline all necessary parameters to calculate gross energy savings for prescriptive residential measures.

### 2.1 Lighting

#### 2.1.1 Interactive Effects

In a home, the implementation of energy efficient lighting products interacts with the energy consumption of other elements such as heating and cooling.

The interactive effects factors for residential lighting products listed in Table 3 below are based on a study conducted by ADS Groupe-Conseil Inc. in 1992 for Hydro-Québec. As presented in Appendix I, the climate data of Nova Scotia and Quebec for the duration of the heating and cooling seasons were analyzed as part of the 2015 evaluation and found to be comparable and thus the study results are applicable for EfficiencyOne (E1) lighting measures.

Table 3 presents the interactive effects factors for five different types of home based on the presence of electrical space heating and air conditioning. For measures offered through Instant Savings where no participant-specific data on heating and cooling systems are available, the interactive effects are based on the weighted average calculated in Table 3.

**Table 3: Interactive Effects Factors for Residential Lighting Products Installed Indoors**

| Type of Home                                         | % of Homes <sup>2</sup> | Energy Interactive Effects Factor <sup>3</sup> | Peak Demand Interactive Effects Factor <sup>4</sup> |
|------------------------------------------------------|-------------------------|------------------------------------------------|-----------------------------------------------------|
| Heat Pump Heating and Air Conditioning               | 38%                     | $-58\% / 1.8 + 6.4\% = -25.8\%$                | -90%                                                |
| Electrical Heating with Air Conditioning             | 2%                      | $-58\% + 3.1\% = -54.9\%$                      | -90%                                                |
| Electrical Heating Without Air Conditioning          | 12%                     | -58%                                           | -90%                                                |
| No Electrical Heating with Air Conditioning          | 5%                      | 3.1%                                           | 0%                                                  |
| With Neither Electrical Heating nor Air Conditioning | 43%                     | 0%                                             | 0%                                                  |
| Weighted Average                                     | 100%                    | -17.7%                                         | -46.8%                                              |

#### Type of Homes

The detailed rationale for interactive effects for heating and cooling follows.

#### Interactive Effects on Electrical Heating

The Hydro-Québec study found that efficient lighting installed in electrically heated single-family homes without air conditioning results in an interactive effects factor for heating of -58%.

<sup>2</sup> Based on 2022-2023 EPI participants. 2021 data were excluded because the separation of electrical and non-electrical savings generated that year skewed the results.

<sup>3</sup> ADS ASSOCIÉS, *Évaluations des effets énergétiques combinés des mesures d'économies d'énergie – résidence unifamiliale*, report presented to Hydro-Québec, 1992.

<sup>4</sup> Based on the ADS report, it is assumed that 10% of the heat is released through exterior walls and ceilings and does not contribute to interactive effects.

## Interactive Effects on Heat Pump Heating

Since the interactive effects factors for electrical heating are based on a heating system efficiency of 100%, some adjustments are necessary for homes that use a heat pump as a primary heating system since the efficiency of this system is superior to 100%.

The interactive effects factor for heating (-58.0%) is divided by 1.8, the COP of a standard mini-split heat pump based on an HSPF2 Region V of 6.0, which is the value for a standard split heat pump as defined by the Federal Energy Efficiency Regulations.<sup>5</sup> This yields an interactive effects factor of -32.2% for heating.

## Interactive Effects on Air Conditioning

The Hydro-Québec study found that efficient lighting installed in homes with air-conditioning units results in an interactive effects factor for cooling of 3.6%. By analyzing the Hydro-Québec study, the Evaluator deduced that the 3.6% was obtained using the following formula.

$$IE_{cooling} = 22\%/COP \times \% \text{ Conditioned Home Area}$$

The value of 22% corresponds to the proportion of the energy savings that occurs during the cooling period and affects the cooling load. It was not possible to extract the exact values used by Hydro-Québec for the COP and the percentage of conditioned home area, but the Evaluator found that a COP for cooling of 2.5 (corresponding to an EER of 8.5) and a percentage of conditioned home area of 40% would be reasonable values. Since the efficiency level of air-conditioning units has increased since the Hydro-Québec study, the Evaluator made an adjustment to increase the COP of 2.5 (EER of 8.5) to a COP of 2.9 (EER of 10), which results in an interactive effects factor for air conditioning of 3.1%.

## Interactive Effects on Heat Pump Cooling

As for cases where cooling is provided by a heat pump, the Evaluator adjusted the cooling interactive effects by dividing the 22% value by the efficiency ratio of mini-split heat pumps and AC units (COP 3.5/2.5). The cooling factor is also multiplied by the ratio of conditioned home area (100%/40%) to account for whole-home conditioning, which is typical of heat pumps. This yields an interactive effects factor of 6.4% for cooling.

## Peak Demand

The Hydro-Québec report assumes that 10% of the heat is released through exterior walls and ceilings and does not contribute to interactive effects. Since the peak demand period occurs during the heating period when lighting and heating systems are assumed to be on, the interactive effects factor for peak demand savings in electrically heated homes is -90%. This factor also applies to homes with heat pumps based on the assumption that heat pumps have a 100% efficiency when operating in very cold conditions, which is typical during peak period conditions.

## Indoor Usage

Lighting products cause interactive effects only if installed indoors. To account for this and obtain an overall interactive effects factor for all lighting products, the percentage of products installed indoors, listed in Table 4, is multiplied by the corresponding interactive effects factor.

## Summary

Combining the values presented in Table 3 and Table 4, Table 5 summarizes the interactive effects factor established for each lighting measure.

<sup>6</sup> Including 9 W, 9.5 W, 10 W, 18 W, and 7 W black-out bulb LED lamps installed through EPI.

<sup>7</sup> Including PAR20, PAR30, GU10, G25, and chandelier E12 LED lamps installed through EPI.

<sup>8</sup> Including ENERGY STAR certified non-A-type lamps rebated through Instant Savings.

<sup>9</sup> Corporate Research Associates Inc., *2016 Socket Study*, Final Report prepared for Efficiency Nova Scotia, December 2016.

<sup>10</sup> Including 9 W, 9.5 W, 10 W, 18 W, and 7 W black-out bulb LED lamps installed through EPI.

<sup>11</sup> Including PAR20, PAR30, GU10, G25, chandelier E12 LED lamps, and LED nightlights installed through EPI.

<sup>12</sup> Including ENERGY STAR certified non-A-type lamps rebated through Instant Savings.

## 2.1.2 Peak Demand Savings Factors

For all indoor and outdoor LED lamps, nightlights, and fixtures, the peak demand-to-energy ratio is based on the Northeast Residential Lighting Hours-of-Use (NERHOU)<sup>13</sup> study, which established a peak-demand-to-energy ratio of 0.162 W/kWh with a peak coincidence factor (PCF) of 16% and 2.7 hours of use per day. The former value is very close to the 0.161 W/kWh established by the EPI Residential Lighting Metering Study,<sup>14</sup> which consisted of a metering study conducted in 2016 and 2017 among 75 households in Nova Scotia to assess the daily hours of operation. Since the margin of error in the NERHOU study was lower and included outdoor lamps in its sample, the Evaluator recommends using 0.162 W/kWh. This value was also used for dimmer switches and solar fixtures.

For motion sensors, peak demand savings were calculated using the peak demand-to-energy ratios developed by Navigant in the 2016-2018 DSM Plan. These ratios were established for various product categories based on modelled system-coincident peak demand savings and energy savings for a projected deployment of products. Navigant used local data to establish the ratios applicable for 2016-2018. The Evaluator recommends using the same ratios during the 2020-2023 DSM cycle.

Table 6 summarizes the peak demand-to-energy ratios established for each lighting measure.

**Table 6: Peak Demand-to-energy Ratios for Residential Lighting Measures**

| Measure         | Peak Demand-to-energy Ratio (W/kWh) | Source                                                       |
|-----------------|-------------------------------------|--------------------------------------------------------------|
| LED Lamps       | 0.162                               | Northeast Residential Lighting Hours-of-Use Study            |
| LED Fixtures    |                                     |                                                              |
| LED Nightlights |                                     |                                                              |

## Electrical Unitary Energy Savings

The equation below determines the unitary savings values of LED lamps for each pairing of old and new wattages. Table 8 lists the parameters and corresponding values used in the equation and the resulting unitary savings values.

$$\text{Energy Savings} \left[ \frac{kWh}{yr} \right] = \frac{(\text{Old Wattage} - \text{New Wattage})[W] \times HOU \left[ \frac{h}{day} \right] \times 365 \left[ \frac{day}{yr} \right]}{1,000 \left[ \frac{W}{kW} \right]}$$

**Table 8: Electrical Unitary Energy Savings Values for LED Lamps**

| Type of LED                                                                  | Old Wattage (W) | New Wattage (W) | Displaced Wattage (W) | Operating Hours (hrs/day) | Unitary Savings Value (kWh/year) |
|------------------------------------------------------------------------------|-----------------|-----------------|-----------------------|---------------------------|----------------------------------|
| EPI                                                                          |                 |                 |                       |                           |                                  |
| 9 W Replacing 25 W                                                           | 25              | 9               | 16                    | 2.6                       | 15.2                             |
| 9 W Replacing 29 W                                                           | 29              | 9               | 20                    |                           | 19.0                             |

| ENERGY STAR Certified LED Non-A-type Lamps (excluding R, BR, and Decorative) | 47.0            | 6.6             | 40.3                  | 2.8                       | 41.3                             |

<sup>15</sup> E1 confirmed during the 2024 DSM evaluation that G25 lamps offered through EPI were now 4.5 W and not 7 W.

## Displaced Wattage

For Efficient Product Installation (EPI), displaced wattage is defined as the difference between the real wattage value of the old lamp and that of the new LED lamp. Both these values are available in the EPI tracking sheet. Previous evaluations confirmed that installed LED lamps had a light output wattage equivalent to that of the replaced lamps for almost all replacements. In other cases, the savings calculations are still based on the difference in real wattage values. For Instant Savings, the average displaced wattage values for the two product categories were established for two types of baselines, namely early replacement, and replace-on-burn-out baselines. For the early replacement scenario, the lamps being replaced are the baseline, while the replace-on-burn-out scenario uses the energy efficiency regulation requirements as the baseline. This methodology is recommended in the principles of the Uniform Methods Project (UMP)<sup>16</sup> to better represent the real baseline wattages for LED lamps.

Since R, BR, and decorative lamps are only available in incandescent and LED, it was assumed that all LED R, BR, and decorative lamps replaced incandescent lamps. It should, however, be noted that the most popular lamp types in that category (ST19 lamps) are required to meet the Energy Efficiency Regulations on general service lamps,<sup>17</sup> which set maximum wattage at 43 W for a 60 W equivalent ST19 lamp for instance. In reality, 43 W ST19 lamps are not available on the market, which explains why this baseline is not used in the unitary savings calculations. Therefore, like previous years, the Evaluator selected to use incandescent decorative lamps as the baseline. The Evaluator noted, as part of the 2023 evaluation, that incandescent decorative lamps were very difficult to find on major retailers' websites. While there might still be participants that replace incandescent lamps early, it is likely at this point that most incandescent lamps have already been replaced (since the standard has been in effect for 9 years). Since 2024 is the last year for the measure, E1 maintained it in the Instant Savings offering.

Other non-A-type lamps are primarily reflector lamps, for which some product types (primarily PAR20 and PAR30) are impacted by the Energy Efficiency Regulations on general service incandescent reflector lamps.<sup>18</sup> For those products, the regulation requires that halogen lamps be more efficient than traditional lamps; effectively, 50 W PAR20 lamps must now consume 39 W or less. The Evaluator assumed that all LED PAR20 lamps replaced standard compliant halogen lamps. Other popular product types include GU10 and PAR16 lamps, which are excluded from this regulation and for which the baseline wattage is the regular halogen wattage.

The equivalent incandescent and halogen wattage values were obtained by researching the recommended equivalencies for the 10 most popular products for each category of LED lamps.

## Hours of Operation

The daily hours of operation value is based on the 2020 Residential Lighting Hours-of-Use Quick Hit Study (RLHOU)<sup>19</sup> in which the data collected through the 2014 Northeast Residential Lighting Hours-of-Use (NERHOU)<sup>20</sup> study is reanalyzed to take into account the effects of efficient lamp saturation on hours of use (HOU). The Evaluator had previously determined that the NERHOU study was the most appropriate for E1 since its findings fell within the margin of error of the metering study conducted by the Evaluator in Nova Scotia, and because the NERHOU sample size was significantly larger than the Nova Scotia study. The newer RLHOU study found that the average runtime is 2.6 hours per day for all types of bulbs and 2.8 hours per day for efficient bulbs given the absence of a snapback effect, compared to respectively 2.7 and 2.9 hours in the NERHOU study.<sup>21</sup>

The NERHOU Study concluded that the daily HOU for all bulb types were 0.3 hours lower than those for high efficiency bulbs. Three theories have been put forward to explain why efficient bulbs are used over a greater number of hours, as follows.

- › Differential socket selection: The assumption is that the most used sockets in a household are selected to install efficient bulbs.
- › Shifting usage: The assumption is that once an efficient bulb is installed, it is favoured over other sockets containing inefficient bulbs.
- › Snapback effect: The assumption is that there is a tendency to use an efficient product more than a replaced inefficient product.

Since there is no indication that one theory overrides the others, each theory is assumed to represent an additional usage of 0.1 hours per day.

Two theories, differential socket selection and shifting usage, apply to bulbs purchased as part of Instant Savings since participants are likely to buy only a limited quantity of bulbs rather than changing every bulb in the house. As for the snapback effect, it is not taken into account in the HOU assessment since this usage would not have occurred if an incandescent or halogen (base case) had been installed in the absence of the program. To avoid overestimating savings by making calculations based on higher operating hours than those of the base case, the Evaluator included an additional usage of 0.2 hours in the daily HOU value determined in the RLHOU Study for all bulb types, thereby increasing the HOU from 2.6 hours to 2.8 hours per day.

For EPI, the HOU are 2.6 hours per day since none of the theories explains a higher HOU for efficient bulbs. Differential socket selection and shifting usage do not apply to EPI since all eligible bulbs are replaced in participants' homes. As in Instant Savings, the snapback effect is not considered to avoid overestimating savings by making calculations based on higher operating hours than those of the base case. The NERHOU study concluded that there was no difference in HOU between single-family homes and apartments. Thus, the HOU applied to obtain unitary savings for both dwelling types are identical.

## Unitary Peak Demand Savings

Unitary peak demand savings are calculated by multiplying the unitary savings value by the peak demand-to-energy ratio.

<sup>19</sup> NMR Group Inc. and DNV GL, *Residential Lighting Hours-of-Use Quick Hit Study*, March 31, 2020.

<sup>20</sup> NMR Group Inc. and DNV GL, *Northeast Residential Lighting Hours-of-Use Study*, May 5, 2014, p. 69.

<sup>21</sup> The snapback effect is an increase in usage following the installation of an efficient product because the operating cost is lower.

**Table 9: Electrical Unitary Peak Demand Savings Values for LED Lamps**

| Type of LED                                                                  | Unitary Energy Savings Value (kWh/year) | Peak Demand-to-energy Ratio (W/kWh) | Unitary Peak Demand Savings Value (W/year) |
|------------------------------------------------------------------------------|-----------------------------------------|-------------------------------------|--------------------------------------------|
| EPI                                                                          |                                         |                                     |                                            |

## Installation Rates

Table 10 lists the installation rate for EPI LED Lamps.

**Table 10: EPI LED Lamp Installation Rate**

| Installation Rate | Margin of Error | Reference                            |
|-------------------|-----------------|--------------------------------------|
| 94%               | 3.0%            | 2024 EPI evaluation (on-site visits) |

For upstream programs like Instant Savings, the UMP makes the following recommendation:

“In-service rates should be calculated through an in-home audit. Since program bulbs cannot be easily identified, the in-service rate can be calculated as the number of installed bulbs purchased in a recent 12-month period divided by the total number of bulbs purchased in the same 12-month period. If the sample size of homes with bulbs purchased in the recent 12-month period is insufficient to provide the necessary levels of confidence and precision, a long-term in-service rate can be used for all bulbs regardless of the time of purchase.”

The UMP provides examples from five recent studies that applied first-year in-service rates to LED upstream programs in the United States. These in-service rates varied between 84% and 99%, with four in-service rates being 95% or higher.

The UMP also mentions three main factors that cause in-service rates below 100%, notably: (1) deeply discounted prices; (2) program inclusion of LED multipacks; and (3) consumers waiting for bulbs to burn out before replacing them. Despite the rebate offered and the large majority (85%) of LED lamps purchased through Instant Savings since 2020 being in packs of two or more, the Evaluator considers it unlikely that most purchased LED lamps are left unused since more than 48% of participants interviewed during the fall online survey mentioned that they purchased lamps to replace functional lamps. The Evaluator also believes that it would not be accurate to use an in-service rate from a program that has a different context and design than Instant Savings.

First-year in-service rates measure the proportion of LED lamps installed within the first year after they are purchased although in-service rates do not capture LED lamps that are installed after that first year. Therefore, if an in-service rate were applied to LED lamp savings, some adjustment would need to be made to account for LED lamps installed after the first year, and the Evaluator believes that the savings deduction would be too low to be considered.

For the abovementioned reasons, in-service rates are not applied to LED lamps and all savings are claimed in the year during which LED lamps were purchased.

## (2) LED Fixtures

### Summary

Table 11 presents a summary of the values used to calculate the savings for motion sensors. The detailed methodology follows.

**Table 11: LED Fixture Measure Summary**

| Parameter                                          | Instant Savings                                                   |                                          |                                                                    | Reference                                                                              |
|----------------------------------------------------|-------------------------------------------------------------------|------------------------------------------|--------------------------------------------------------------------|----------------------------------------------------------------------------------------|
|                                                    | ENERGY STAR<br>Certified LED<br>Recessed<br>Downlight<br>Fixtures | ENERGY STAR<br>Certified LED<br>Fixtures | ENERGY STAR<br>Certified LED<br>Fixtures with<br>Motion<br>Sensors |                                                                                        |
| Measure Description and Identification             |                                                                   |                                          |                                                                    |                                                                                        |
| Measure                                            | LED fixtures rebated in store                                     |                                          |                                                                    | -                                                                                      |
| Baseline                                           | Standard-compliant new fixtures                                   |                                          |                                                                    |                                                                                        |

| Interactive Effects Factor for Peak Demand Savings | -46.8%                                                            | -46.8%                                   | -1.4%                                                              | See Subsection 2.1.1                                                                   |

### Electrical Unitary Energy Savings

The equation below determines the unitary savings values of LED fixtures. Table 12 lists the parameters and corresponding values used in the equation and the resulting unitary savings values.

$$\begin{aligned}
 & \text{Energy Savings} \left[ \frac{kWh}{yr} \right] \\
 &= \frac{\left( \text{Wattage}_{average\ equivalent} [W] \times HOU_{old} \left[ \frac{hrs}{day} \right] - \text{Wattage}_{average} [W] \times HOU_{new} \left[ \frac{hrs}{day} \right] \right) \times 365 \left[ \frac{day}{yr} \right]}{1,000 \left[ \frac{W}{kW} \right]}
 \end{aligned}$$

**Table 12: Electrical Unitary Savings Values for LED Fixtures**

| Type of LED Fixture                                    | Average Wattage (W) | Average Equivalent Wattage (W) | Displaced Wattage (W) | Old Operating Hours (hrs/day) | New Operating Hours (hrs/day) | Unitary Savings Value (kWh/year) |
|--------------------------------------------------------|---------------------|--------------------------------|-----------------------|-------------------------------|-------------------------------|----------------------------------|
| ENERGY STAR Certified LED Recessed Downlight Fixtures  | 12.5                | 64.2                           | 51.7                  | 2.8                           | 2.8                           | 52.8                             |
| ENERGY STAR Certified LED Fixtures                     | 27.0                | 109                            | 82.0                  |                               |                               | 83.8                             |
| ENERGY STAR Certified LED Fixtures with Motion Sensors | 22.4                | 131                            | 109                   | 4.69                          | 2.90                          | 201                              |

### Displaced Wattage

To establish the displaced wattage of each category of lighting fixture offered under Instant Savings, the Evaluator identified the best-selling models listed in the 2024 tracking sheet for each type of LED fixture.

The 10 best-selling models of LED recessed downlight fixtures represent over 93% of all recessed LED lamps sold through Instant Savings. All of these fixtures replaced fixtures that would have housed small halogen reflector lamps, typically MR16 or PAR16. All fixtures were found to have lumen outputs well above that of standard 50 W MR15 (which is around 400-450 lm). However, since fixtures are likely to be replaced one for one, the Evaluator selected a baseline wattage corresponding to the brightest reflector lamps typically used indoor, a 60 W MR16.

The Evaluator selected the 10 most popular models that represent 79% of all 2024 sales for ENERGY STAR Certified LED Fixtures without motion sensors. Most of these fixtures replace fixtures that would have housed incandescent A19 lamps. The Evaluator used the light output measured in lumens found on ENERGY STAR and manufacturer websites and used a table from the ENERGY STAR website to establish equivalent incandescent wattages (see Table 13 below).

**Table 13: 2022 ENERGY STAR Certified Lamp Light Output Equivalency to Incandescent Lamp Wattage<sup>22</sup>**

| Old Incandescent Lamps (W) | ENERGY STAR Certified Lamp Light Output (Lumens) |
|----------------------------|--------------------------------------------------|
| 40                         | 450                                              |
| 60                         | 800                                              |
| 75                         | 1,100                                            |
| 100                        | 1,600                                            |
| 150                        | 2,600                                            |

The Evaluator analyzed the eleven best-selling models of ENERGY STAR certified LED fixtures with a motion sensor, which represent 89% (excluding solar fixtures) of all 2024 sales for this product category. The Evaluator found that 97% of those fixtures housed lamps that replaced halogen lamps, while 3% of them replaced incandescent lamps.<sup>23</sup>

## Hours of Operation

The daily hours of operation value is based on the 2020 Residential Lighting Hours-of-Use Quick Hit Study (RLHOU)<sup>24</sup> in which the data collected through the 2014 Northeast Residential Lighting Hours-of-Use (NERHOU)<sup>25</sup> study is reanalyzed. This newer study established an average use of 2.8 hours per day for efficient bulbs given the absence of a snapback effect.<sup>26</sup>

The UMP Residential Lighting Evaluation Protocol recommends that each jurisdiction conduct a metering study to determine specific hours of use (HOU). In 2016 and 2017, the Evaluator conducted a metering study among 75 households to assess daily hours of operation. The overall average daily HOU was established at 2.48 hours/day with a margin of error of  $\pm 0.24$  hours/day. Since the NERHOU Study was conducted on a much larger scale with 848 households and the study data and findings are closely aligned with the Evaluator's metering study margin of error, the Evaluator decided that the values established by the NERHOU Study are still the most appropriate for LED lamps installed through Instant Savings. For 2024, Evaluator used the updated average hours of operation value for efficient lamps without a snapback value, which is 2.8 hours per day.

For 2024, the Evaluator found that 97% of the LED fixtures equipped with a motion sensor are designed for outdoor usage. For LED fixtures installed outdoors, the old and new hours of operation used are 4.75 and 2.95 hours per day respectively.<sup>27</sup> For LED fixtures installed indoors, the old and new hours of operation used are 2.6 and 1.2 hours per day respectively (where 1.2 hours is calculated based on the 54% reduction in operating time).<sup>28</sup> When accounting for the weight of indoor and outdoor fixtures, the average old and new hours of operation were established at 4.69 and 2.90 respectively.

## Installation Rates

The installation rate is assumed to be 100%.

<sup>25</sup> NMR Group Inc. and DNV GL, *Northeast Residential Lighting Hours-of-Use Study*, May 5, 2014, p. 69.

<sup>26</sup> The snapback effect is an increase in usage following the installation of an efficient product because the operating cost is lower.

#### Electrical Unitary Energy Savings

The unitary savings value for dimmer switches is based on the general lighting equation adapted as follows to consider the effect of dimming on energy consumption.

$$Energy\ Savings\ \left[ \frac{kWh}{yr} \right] = \frac{(Average\ Wattage)[W] \times \%Dimmed \times HOU \left[ \frac{h}{day} \right] \times 365 \left[ \frac{day}{yr} \right]}{1,000 \left[ \frac{W}{kW} \right]}$$

The value for each parameter and resulting unitary savings value are summarized in Table 15.

**Table 15: Electrical Unitary Savings Values for Dimmer Switches**

| Parameter                         | Instant Savings     | EPI              | Reference                                                                                                                                                                                                                                                                                                                                                                |

### Electrical Unitary Energy Savings

Different unitary savings values apply according to the location of the motion sensor and additional devices.

## Indoor Motion Sensors

The unitary savings value for indoor motion sensors is based on the general lighting equation adapted as follows to consider the effect of motion sensing on energy consumption.

$$\text{Energy Savings} \left[ \frac{kWh}{yr} \right] = \frac{(\text{Average Wattage})[W] \times HOU \left[ \frac{h}{day} \right] \times \%HOU \text{ Reduction} \times 365 \left[ \frac{day}{yr} \right]}{1,000 \left[ \frac{W}{kW} \right]}$$

The value for each parameter and resulting unitary savings value are summarized in Table 17.

**Table 17: Electrical Unitary Savings Values for Indoor Motion Sensors**

| Parameter                                 | Instant Savings     | EPI              | Reference                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Unitary Energy Savings [kWh/year]</b>  | <b>22.1</b>         | <b>9.22</b>      | <b>Calculation</b>                                                                                                                                                                                                                                                                                                                                                              |

## Indoor Motion Sensors with Dimmer Switch

The unitary savings value for indoor motion sensors is based on the general lighting equation adapted as follows to consider the effects of motion sensing and dimming on energy consumption. The annual energy savings corresponds to the difference between the base consumption and the reduced consumption occurring with the motion sensor and dimmer switch.

$$\text{Energy Savings [kWh/yr]} = \text{Base Consumption} - \text{Reduced Consumption}$$

$$\begin{aligned} \text{Base Consumption [kWh/yr]} \\ = ((\text{Average Wattage})[W] \times HOU[h/day] \times 365[day/yr]) / 1,000[W/kW] \end{aligned}$$

$$\begin{aligned} \text{Reduced Consumption [kWh/yr]} \\ = ((\text{Average Wattage})[W] \times (1 - \%Dimmed) \times HOU[h/day] \\ \times (1 - \%HOU \text{ Reduction}) \times 365[day/yr]) / 1,000[W/kW] \end{aligned}$$

The value for each parameter and resulting unitary savings value are summarized in Table 18 below.
