| <b>Unitary Energy Savings [kWh/year]</b>  | <b>25.9</b>         | <b>Calculation</b>                                                                                                                                            |

## Outdoor Motion Sensors

The unitary savings value for outdoor motion sensors is based on the general lighting equation adapted as follows to consider the effect of motion sensing on energy consumption.

$$\text{Energy Savings} \left[ \frac{kWh}{yr} \right] = \frac{(\text{Average Wattage})[W] \times (\text{Old HOU} - \text{New HOU}) \left[ \frac{h}{day} \right] \times 365 \left[ \frac{day}{yr} \right]}{1,000 \left[ \frac{W}{kW} \right]}$$

The value for each parameter and resulting unitary savings value are summarized in Table 19.

**Table 19: Unitary Savings Values for Outdoor Motion Sensors**

| Parameter                                | Instant Savings                                | EPI               | Reference                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------|------------------------------------------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Average Wattage [W]                      | (85% x 2 x 44.6 W) + (15% x 2 x 21.6) = 82.3 W | 2 x 15 W = 30.0 W | Assumed two controlled lamps per motion sensor<br><u>Instant Savings</u> : Assumed 85% of outdoor lighting for security spotlights with an average wattage of 44.6 W as indicated through the representative lamp mix calculation in Table 20. Assumed the remaining 15% for porch lighting with the weighted average wattage of 21.6 W as observed by the United States Department of Energy <sup>39</sup><br><u>EPI</u> : Standard outdoor LED wattage (PAR38) <sup>40</sup> assuming the motion sensor controls lamps were LED or replaced by LED through EPI |
| Old Operating Time [hrs/day]             | 4.75                                           |                   | 2011 OPA Prescriptive Measures and Assumptions List <sup>41</sup>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| New Operating Time [hrs/day]             | 2.95                                           |                   | 2011 OPA Prescriptive Measures and Assumptions List <sup>42</sup>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Unitary Energy Savings [kWh/year]</b> | <b>54.1</b>                                    | <b>19.7</b>       | <b>Calculation</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Installation Rate                                  | 94%                                                                                    | See details below under Installation Rates                                             |
| Effective Useful Life [years]                      | 1.0                                                                                    | See Subsection 3.1                                                                     |
| Electrical Savings Parameters                      |                                                                                        |                                                                                        |
| Unitary Energy Savings [kWh/year]                  | 29.3                                                                                   | See details below under Electrical Unitary Energy Savings                              |
| Peak Demand-to-energy Ratio [W/kWh]                | 0.162                                                                                  | See Subsection 2.1.2                                                                   |
| Unitary Peak Demand Savings [W]                    | 4.75                                                                                   | Calculated by multiplying the unitary savings value by the peak demand-to-energy ratio |
| Interactive Effects Factor for Energy Savings      | Calculation based on home heating and air-conditioning systems for each installed unit | See Subsection 2.1.1                                                                   |
| Interactive Effects Factor for Peak Demand Savings |                                                                                        |                                                                                        |

### Electrical Unitary Energy Savings

Table 22 lists the parameters and corresponding values used in the equation below for LED nightlights and the resulting unitary values. The values for displaced wattages and hours of operation are consistent with the values used by other jurisdictions such as the State of Pennsylvania.<sup>44</sup>

$$\text{Energy Savings} \left[ \frac{kWh}{yr} \right] = \frac{(\text{Old Wattage} - \text{New Wattage})[W] \times HOU \left[ \frac{h}{day} \right] \times 365 \left[ \frac{day}{yr} \right]}{1,000 \left[ \frac{W}{kW} \right]}$$

<sup>44</sup> Pennsylvania Public Utility Commission, *Technical Reference Manual Volume 2: Residential Measures*, August 2019 (revised February 2021), p. 8.

**Table 22: Electrical Unitary Savings Values for LED Nightlights**

| Parameter                         | Value | Reference                                                                   |
|-----------------------------------|-------|-----------------------------------------------------------------------------|
| Old Wattage [W]                   | 7.0   | Assumption based on the typical wattage value of an incandescent nightlight |
| New Wattage [W]                   | 0.3   | Wattage value of the LED nightlight installed through EPI (E1)              |
| Average Displaced Wattage [W]     | 6.7   | Calculation                                                                 |
| Hours of Operation [hrs/day]      | 12    | Assumption based on the average length of night                             |
| Unitary Energy Savings [kWh/year] | 29.3  | Calculation                                                                 |

## Installation Rates

Table 23 lists the installation rate for EPI LED nightlights.

**Table 23: EPI LED Nightlight Installation Rate**

| Installation Rate | Margin of Error | Reference                            |
|-------------------|-----------------|--------------------------------------|
| 94%               | 3.0%            | 2024 EPI evaluation (on-site visits) |

## (6) Solar Fixtures

### Summary

Table 24 presents a summary of the values used to calculate the savings for solar fixtures. The detailed methodology follows.

**Table 24: Solar Fixture Measure Summary**

| Parameter                                          | Instant Savings                                                                         | EPI                                                  | Reference                                                                              |

## Electrical Unitary Energy Savings

Since solar fixtures consume no electricity from the grid, all the electrical energy consumed by the baseline fixture is saved. The only solar fixtures currently offered are outdoor security fixtures with motion sensors.

The unitary savings value for solar fixtures with motion sensors is based on the outdoor motion sensor equation adapted as follows to consider the nil consumption of the new fixtures.

$$Energy\ Savings\ \left[\frac{kWh}{yr}\right] = \frac{Baseline\ Wattage\ [W] \times Old\ HOU\ \left[\frac{h}{day}\right] \times 365\ \left[\frac{day}{yr}\right]}{1,000\ \left[\frac{W}{kW}\right]}$$

The value for each parameter and resulting unitary savings value are summarized in Table 25.

<sup>45</sup> For solar fixtures, E1 requires electricians to replace non-LED outdoor fixtures only.

**Table 25: Unitary Savings Values for Solar Fixtures**

| Parameter                         | Instant Savings | EPI  | Reference                                                                                                                                                                               |
|-----------------------------------|-----------------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## 2.2 Water Heating

### 2.2.1 Interactive Effects

#### Hot Water Insulation Measures

For hot water insulation measures, namely pipe insulation and hot water tank wraps, the interactive effects factors are based on engineering calculations to account for the duration of the heating and cooling seasons, cooling and heating system efficiency, and the percentage of heat generated inside the heated portion of the building envelope.

This section contains the detailed methodology for calculating interactive effects as well as the rationale for interactive effects for single-family homes and apartments. The distinction between interactive effects for these two types of dwellings comes from the assumption that domestic hot water (DHW) insulation measures are more likely to be installed in conditioned spaces in apartments than in single-family homes.

#### Single-family Homes

Based on site visit results from the 2015 evaluation<sup>48</sup> and accounting for the proportion of DHW insulation measures installed in conditioned spaces, the average number of months during which heating interactive effects occur in a single-family home is 3.8 months. It is assumed that the impact of DHW on cooling loads is negligible since most measures were installed in basements or garages, which might be heated but are rarely air-conditioned. Similar to lighting measures, it is assumed that 10% of the heat released by the pipes and DHW is lost through exterior walls and ceilings and does not contribute to the interactive effects.

For single-family homes with heat pump heating, since the interactive effects factors are based on a heating system efficiency of 100%, some adjustments are necessary for homes that use a heat pump as a primary heating system because the efficiency of such systems is superior to 100%. To do so, the interactive effects factor for heating (-28.5%) is divided by 1.8, the COP of a standard mini-split heat pump based on an HSPF2 Region V of 6.0, which is the value for a standard split heat pump as defined by the Federal Energy Efficiency Regulations.<sup>49</sup>

#### Apartments

Based on the assumption that DHW insulation measures are installed in conditioned spaces, a heating period of eight months was used as the average number of months during which heating interactive effects occur in an apartment. Similarly, cooling interactive effects occur for the duration of the cooling period, which is two months.

To adjust the potential interactive effects on air-conditioning systems, the Evaluator used an average COP of 3.5 for apartments with heat pumps and a COP of 2.9 for apartments with air conditioning, which are consistent with the assumptions outlined in Subsection 2.1.1.

#### Peak Demand

As for the impact on peak demand savings, it is assumed that all the DHW tanks in a conditioned or semi-conditioned space create interactive effects. Therefore, similar to lighting products, the interactive effects factor for peak demand savings in electrically heated homes is -90%.

|                     | With Neither Electrical Heating nor Air Conditioning | 0.0%                                             | 0.0%                                             | 0.0%                             | 0%                              |

## Other DHW Measures

For the remaining DHW measures, interactive effects are nil, with the exception of HPWHs. For HPWH measures, interactive effects are already included in the engineering equation used to calculate the unitary savings value. Therefore, no additional interactive effects factor is applied to those savings.

## Summary

Table 28 summarizes the interactive effects factors established for each water heating measure.

**Table 28: Interactive Effects Factors for Water Heating Measures**

| Measure                                | Type of Home                                                    | Interactive Effects Factors for Energy Savings | Interactive Effects Factors for Peak Demand Savings | Source                                                          |

## 2.2.2 Peak Demand Savings Factors

For most water heating measures, peak demand savings are calculated using the peak demand-to-energy ratios developed by Navigant in the 2016-2018 DSM Plan. These ratios were established for various product categories based on modelled system-coincident peak demand savings and electrical energy savings for a projected deployment of products. Navigant used local data to establish the ratios applicable for the 2016-2018 period. The Evaluator recommends using the same ratios during the 2023-2025 DSM cycle, since this end-use load shape is unlikely to have changed significantly since 2026.

For solar domestic hot water (DHW), the peak demand-to-energy ratio is nil. Solar DHW systems provide no peak demand savings because the sun has set during the peak demand period.

Table 29 summarizes the peak demand-to-energy ratios established for each water heating measure.

**Table 29: Peak Demand-to-energy Ratios for Water Heating Measures**

| Measure                   | Peak Demand-to-energy Ratio (W/kWh) | Source                                                                                                 |
|---------------------------|-------------------------------------|--------------------------------------------------------------------------------------------------------|
| Drain Water Heat Recovery | 0.162                               | RES-Water Heat, Navigant 2016-2018 DSM Plan                                                            |
| Heat Pump Water Heater    |                                     |                                                                                                        |
| Low-flow Showerhead       |                                     |                                                                                                        |
| Faucet Aerator            |                                     |                                                                                                        |
| Thermostatic Shower Valve |                                     |                                                                                                        |

## 2.2.3 Water Heating Measures

### (1) Drain Water Heat Recovery

#### Summary

Table 30 presents a summary of the values used to calculate drain water heat recovery (DWHR) savings. The detailed methodology follows.

**Table 30: Drain Water Heat Recovery Measure Summary**

| Parameter                                          | MHEEP                                                                       | Reference                                                                              |
|----------------------------------------------------|-----------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Measure Description and Identification             |                                                                             |                                                                                        |
| Measure                                            | Drain water heat recovery for electric DHW heating with direct installation | -                                                                                      |
| Baseline                                           | Shower drains without drain water heat recovery                             |                                                                                        |
| General Parameters                                 |                                                                             |                                                                                        |
| Installation Rate                                  | 100%                                                                        | See details below under Installation Rates                                             |
| Effective Useful Life [years]                      | 20                                                                          | See Subsection 3.2                                                                     |
| Electrical Savings Parameters                      |                                                                             |                                                                                        |
| Unitary Energy Savings [kWh/year]                  | 599                                                                         | See details below under Electrical Unitary Energy Savings                              |
| Peak Demand-to-energy Ratio [W/kWh]                | 0.162                                                                       | See Subsection 2.2.2                                                                   |
| Unitary Peak Demand Savings [W]                    | 97.0                                                                        | Calculated by multiplying the unitary savings value by the peak demand-to-energy ratio |
| Interactive Effects Factor for Energy Savings      | 0%                                                                          | See Subsection 2.2.1                                                                   |
| Interactive Effects Factor for Peak Demand Savings | 0%                                                                          | See subsection 2.2.1                                                                   |

## Electrical Unitary Energy Savings

The DWHR unitary savings values were determined using the HOT2000 simulation tool since it includes DWHR as an option. Although a typical single-family home and multifamily building were modelled, the savings for DWHR were the same regardless of the building type when looking at savings per occupant. The unitary savings values were obtained using the equation below and the values presented in Table 31 afterwards.

$$\text{Energy Savings}_{kWh} = \text{Savings per Occupant} \times \text{Number of Persons per Household}$$

**Table 31: Electrical Unitary Energy Savings Values for Drain Water Heat Recovery Systems**

| Parameter                                       | MHEEP | Reference                          |
|-------------------------------------------------|-------|------------------------------------|
| <b>Inputs to the HOT2000 Simulation</b>         |       |                                    |
| Number of Showers per Person per Day [shower]   | 0.67  | Mayer, Oreo et al. <sup>50</sup>   |
| Average Shower Duration <sup>51</sup> [minutes] | 8     | DeOreo et al. <sup>52</sup>        |
| Shower Flow Rate [litres/minute]                | 9.5   | 2019 Connecticut TRM <sup>53</sup> |
| <b>Energy Savings Calculation</b>               |       |                                    |
| Number of Persons per Household [person]        | 3.6   | 2022 MHEEP tracking sheet          |
| Energy Savings per Occupant [kWh/person]        | 166.4 | HOT2000 simulations                |
| Unitary Energy Savings [kWh/year]               | 599   | Calculated                         |

## Installation Rates

Installation rates for drain water heat recovery systems are estimated at 100% because they are installed by MHEEP contractors.

### Electrical Unitary Energy Savings

The unitary savings value for solar DHW systems installed through Green Heat is calculated for each system using a custom RETScreen model.

### Unitary Peak Demand Savings

Solar DHW systems provide no peak demand savings because the sun has set during the peak demand period.

### Installation Rates

Installation rates for solar DHW systems are estimated at 100% due to their relatively high cost.

### (3) Heat Pump Water Heaters

#### Summary

Table 33 presents a summary of the values used to calculate heat pump water heater (HPWH) savings. Savings are included for a market transformation HPWH program, in addition to other resource acquisition program components. The detailed methodology follows.

**Table 33: Heat Pump Water Heater Measure Summary**

| Parameter                                          | HEA, MHEEP                                                                                                                                                                                                                    |                                             |                                   | Instant Savings, HPWH                                                              |                                                                                        | Reference |

## Electrical Unitary Energy Savings

The unitary savings for HPWHs are taken from a metering study conducted for NEEA.<sup>54</sup> They include interactive effects. Instant Savings Average Unitary Energy Savings is a weighted average based on the share of space heating systems in Nova Scotia; it calculates the electric energy savings only, by taking into account the proportion of replaced water heaters that electric water heaters among households that have non-electric, electric resistance and heat pump space heating.

Table 34 below lists the equation parameters and corresponding values, as well as the resulting unitary savings values.

## Installation Rates

Installation rates for heat pump water heaters are estimated at 100% due to their relatively high cost.

<sup>55</sup> Ecotope inc., *NEEA Heat Pump Water Heater Model Validation Study*, 2015, p. 72.

Average of 3 non-ducted models in heating zone 3 (most comparable to Nova Scotia). All water heaters are assumed to be in heated spaces since HEA tracking sheet shows that is the case for more than 98% of homes. Used Interior "EFAF" for electric resistance space heating, "interior HP" for heat pumps space heating and "interior gas" for non-electrical space heating.

<sup>56</sup> The proportions of electric water heating published by NRCAN are not consistent and significantly lower than the value obtained from EPI participants. Therefore, the proportion of electrical water heating is based on EPI tracking sheet data.

<sup>57</sup> Given the change in the EPI program in 2021, the data for the proportion of electric water heating didn't reflect what was previously observed. Therefore, data from only the 2022 and 2023 EPI tracking sheets were used.

## Electrical Unitary Energy Savings

The equations below are used to determine the annual unitary savings values for low-flow showerheads. The reduction in domestic hot water consumption is established by the difference between the base and efficient domestic hot water consumption levels, as presented in the second equation.

$$\begin{aligned} \text{Energy Savings} \left[ \frac{kWh}{year} \right] &= \text{DHW Reduction} \left[ \frac{gal}{day} \right] \times \frac{1}{\eta} \times Cp_{H2O} \left[ \frac{Btu}{lb \cdot ^\circ F} \right] \times \rho_{H2O} \left[ \frac{lb}{ft^3} \right] \times \Delta T_{H2O} [^\circ F] \times n_{days} \left[ \frac{days}{year} \right] \\ &\times UC1 \left[ \frac{kWh}{Btu} \right] \times UC2 \left[ \frac{ft^3}{gal} \right] \times \%DWH_{elec} \\ \text{DHW Reduction} \left[ \frac{gal}{day} \right] &= (q_{base} - q_{low}) [gpm] \times \frac{n_{people} [person]}{n_{showerheads}} \times \%DHW \times t_{shower} \left[ \frac{min}{shower} \right] \\ &\times n_{shower} \left[ \frac{shower}{day \cdot person} \right] \end{aligned}$$

Table 36 below lists the parameters and corresponding values applied in the equations above for low-flow showerheads and the resulting unitary savings values.

**Table 36: Electrical Unitary Energy Savings Values for Low-flow Showerheads**

| Parameter                                                        | Symbol            | EPI                                      |                                          | Reference                                                                           |

### Electrical Unitary Energy Savings

The equation below is used to calculate the annual unitary savings value for faucet aerators.

$$\begin{aligned}
 & \text{Energy Savings} \left[ \frac{kWh}{yr} \right] \\
 &= \frac{(DHW_{base} - DHW_{efficient}) \left[ \frac{gal}{day} \right] \times Cp_{H_2O} \left[ \frac{BTU}{lb^{\circ}F} \right] \times \rho_{H_2O} \left[ \frac{lb}{ft^3} \right] \times \Delta T_{H_2O} [^{\circ}F] \times n_{days} \left[ \frac{days}{yr} \right] \times UC1 \left[ \frac{kWh}{BTU} \right] \times UC2 \left[ \frac{ft^3}{gal} \right]}{\eta}
 \end{aligned}$$

The base domestic hot water consumption value ( $DHW_{base}$ ) is calculated with the equation below:

$$DHW_{base} \left[ \frac{gal}{day} \right] = \frac{DW_{person} \left[ \frac{gal}{day \cdot person} \right] \times n_{people} [person] \times \%_{DHW}}{n_{faucets}}$$

The efficient domestic hot water consumption value ( $DHW_{efficient}$ ) is calculated by using the baseline flow rate ( $q_{base}$ ), low-flow rate ( $q_{low}$ ), and base domestic hot water consumption value, as illustrated in the equation below:

$$DHW_{efficient} \left[ \frac{gal}{day} \right] = DHW_{base} \left[ \frac{gal}{day} \right] \times \left( 1 - \frac{q_{base} - q_{low}}{q_{base}} \right)$$

Table 40 lists the parameters and values applied in the three equations above for faucet aerators and the resulting unitary savings values.

**Table 40: Electrical Unitary Savings Values for Faucet Aerators**

| Parameter                                        | Symbol            | Value for Single-family Homes | Value for Apartments | Source                                                                                                                             |

## Electrical Unitary Energy Savings

The equation below is used to determine the annual unitary savings values for thermostatic shower valves. Energy savings are established by calculating the reduction in domestic hot water usage, as presented in the second equation below.

$$DHW \text{ Reduction } \left[ \frac{gal}{year} \right] = q \left[ \frac{gal}{min} \right] \times n_{people} [person] \times \%_{DHW} \times t_w \left[ \frac{min}{shower} \right] \times n_{shower} \left[ \frac{shower}{day \cdot person} \right] \times \frac{1}{n_{showerhead}}$$

Table 43 below lists the parameters and corresponding values applied to the two equations above and the resulting unitary savings values for thermostatic shower valves.

**Table 43: Electrical Unitary Energy Savings Values for Thermostatic Shower Valves**

| Parameter                                                        | Symbol               | Value for Single-family Homes | Value for Apartments | Reference                                                              |

| Unitary Peak Demand Savings [W]                    | 2.06                                                                                       | Calculated by multiplying the unitary savings value by the peak demand-to-energy ratio |
| Interactive Effects Factor for Energy Savings      | Calculation based on home heating and air-conditioning systems for each installed unit     | See Subsection 2.2.1                                                                   |
| Interactive Effects Factor for Peak Demand Savings |                                                                                            |                                                                                        |

### Electrical Unitary Energy Savings

As presented in Table 46, the annual unitary savings value for pipe insulation was identified through Ontario Power Authority (OPA) 2011<sup>75</sup> values and amounts, established at 12.7 kWh per linear foot.

**Table 46: Unitary Savings Value for Pipe Insulation**

| Parameter                                  | EPI  |
|--------------------------------------------|------|
| Unitary Energy Savings (per ft) [kWh/year] | 12.7 |

<sup>75</sup> Ontario Power Authority (OPA), *2011 Prescriptive Measures and Assumptions Version 1*, March 2011, p. 542.

## Installation Rates

Table 47 lists the installation rate for EPI pipe insulation.

## Electrical Unitary Energy Savings

The following equations are used to determine the annual unitary savings associated with hot water tank wraps. The energy savings are equal to the difference in heat losses associated with tank circumference ( $Q_{\text{tank}}$ ) before and after adding the tank wrap ( $Q_{\text{tank+RSI 1.21}}$ ). The heat losses are calculated using the following formulas of heat transfer in an insulated cylinder:

$$R_{\text{layer}} = \frac{\ln(r_e/r_i)}{2\pi k}$$

$$R_{\text{cyl}} = R_{\text{layer1}} + R_{\text{layer2}}$$

$$Q_{\text{cyl}} = \frac{T_i - T_e}{R_{\text{cyl}}} L$$

$$Q_{\text{top}} = \frac{A_{\text{top}} \times (T_i - T_e)}{R_{\text{top}}}$$

$$Q_{\text{total}} = Q_{\text{cyl}} + Q_{\text{top}}$$

$$\text{Energy Savings}_{\text{kWh}} = \frac{(Q_{\text{total}}) \cdot \text{HOU}}{\eta_{\text{heater}}}$$

The calculation considers a typical domestic tank with a capacity of 60 imperial gallons and a hot water tank wrap with a thermal resistance of 1.21 m<sup>2</sup>·°C/W.

Table 49 lists the values applied in equations presented above to obtain the unitary savings for tank wraps.

**Table 49: Electrical Unitary Savings Values for Hot Water Tank Wraps**

| Parameter                                                                                                                              | Symbol              | Value for Single-family Homes | Value for Apartments | Reference                                                                 |

## 2.3 Space Heating

### 2.3.1 Interactive Effects

Since space heating measures target heating and cooling loads directly, the impact of these measures on heating and cooling is considered in the unitary savings. Therefore, as presented in Table 51, the interactive effects factors for each space heating measure are assumed to be nil.

**Table 51: Interactive Effects Factors for Space Heating Measures**

| Measure                                                   | Interactive Effects Factor for Energy Savings | Interactive Effects Factor for Peak Demand Savings | Source                                                                                                               |

## 2.3.2 Peak Demand Savings Factors

For most space heating measures, peak demand savings are not calculated using a peak demand-to-energy ratio. For more details, refer to Subsection 1.1.1(1) for mini-split heat pumps, Subsection 1.1.1(2) for central-air-source heat pumps, Subsection 1.1.1(3) for ground-source heat pumps, Subsection 1.1.1(4) for wood and pellet stoves and fireplace inserts, and Subsection 1.1.1(5) for wood and pellet boilers and furnaces.

For air sealing products, peak demand savings are calculated using a peak demand-to-energy ratio developed by Navigant in the 2016-2018 DSM Plan. These ratios were established for various product categories based on modelled system-coincident peak demand savings and electrical energy savings for a projected deployment of products. Navigant used local data to establish the ratios applicable for the 2016-2018 period. The Evaluator recommends using the same ratios during the 2020-2023 DSM cycle.

For programmable thermostats, several studies demonstrate peak demand savings when there are specific interventions to adjust heating operating times to minimize redundancy with the system peak. However, when there is no specific intervention related to the installation of programmable thermostats, the impact on the system peak is often assumed to be nil. Only one study was referenced with winter peak demand savings, but these demand savings were very low and difficult to replicate to the Nova Scotia market. Therefore, the peak demand-to-energy ratio for programmable thermostats is established at 0 kW/kWh.

For solar air heating, the peak demand-to-energy ratio is nil. Solar systems provide no peak demand savings because the sun has set during the peak demand period.

For smart thermostats, similar to programmable thermostats, the impact on the system peak is assumed to be nil since no specific intervention to minimize redundancy of operation with the system peak is in place. Therefore, the peak demand-to-energy ratio for smart thermostats is established at 0 W/kWh.

A literature review of programmable and smart thermostat peak demand savings found that nil peak demand savings is the most common assumption among other jurisdictions when thermostats are installed with no specific demand response intervention. In other words, peak demand savings for thermostats are assumed to be nil unless participants are taking part in a demand response program.

Table 52 summarizes the peak demand-to-energy ratios established for each space heating measure.

**Table 52: Peak Demand-to-energy Ratios for Space Heating Measures**

| Measure                                      | Peak Demand-to-energy Ratio (W/kWh) | Reference                                               |

## 2.3.3 Space Heating Measures

### (1) Mini-split Heat Pumps

#### Summary

Table 53 presents a summary of the values used to calculate mini-split heat pump (MSHP) savings. The detailed methodology follows.

**Table 53: Mini-split Heat Pump Measure Summary**

| Parameter                                          | Green Heat, ASFH                                                                                                                     |                                                                             | HEA                                                         | MHEEP                                                                     | Reference                                                 |

## Electrical Unitary Energy Savings

For Green Heat, the electrical unitary energy savings for MSHPs are based on the billing analysis results of the 2024 Green Heat evaluation, which yielded savings per unit of capacity for both homes that were fully electrically heated and homes that were only mainly electrically heated (e.g. that had secondary non-electrical heating systems such as wood stoves. Note that fireplaces are not considered as non-electrical secondary heating systems for the purpose of the billing analyses, and households with such systems still fall in the fully electrically heated category). The billing analysis results yield unitary savings values of 0.0855 kWh/Btu/h for fully electrically heated households and nil savings for mainly electrically heated homes. The appropriate unitary savings value is then multiplied by the heating capacity of the MSHP (found in the tracking sheet) and is used to calculate an energy savings value specific to each MSHP. Further details on the billing analysis methodology and results are found in the appendices of the 2024 DSM Existing Residential Evaluation Report.

For HEA and MHEEP, the electrical energy savings are based on HOT2000 simulation outputs that are multiplied by adjustment ratios obtained through a billing analysis conducted for the 2024 DSM evaluation of HEA, as listed in Table 54 below. These adjustment ratios apply to all HOT2000 modelled savings (i.e. including savings from measures other than heat pumps).

**Table 54: Adjustment Ratios for HEA and MHEEP Modelled Savings**

| Scenario                                                                            | Adjustment Ratio |
|-------------------------------------------------------------------------------------|------------------|
| A participant who registered <b>with</b> a heat pump                                | 1.24             |
| A participant who registered <b>without</b> a heat pump and who did not install one | 0.58             |
| A participant who registered <b>without</b> a heat pump and then had one installed  | 0.43             |

## Unitary Peak Demand Savings

For Green Heat and HEA, the unitary peak demand unitary savings for MSHPs are calculated using the variables defined and listed in the equation and Table 55 below.

$$Peak\ Demand\ Savings_W = \frac{1,000}{3.412} \times HC_{min} \times \left( \frac{1}{COP_{base\_min}} - \frac{1}{COP_{ee\_min}} \right)$$

**Table 55: Unitary Peak Demand Savings Values for Mini-split Heat Pumps**

| Variable                                                                                            | Symbol            | Green Heat                                   | Reference                           |
|-----------------------------------------------------------------------------------------------------|-------------------|----------------------------------------------|-------------------------------------|
| Rated heating capacity of the new heat pump at outdoor air temperature of -15°C [kBtu/h]            | $HC_{min}$        | Specification data for each installed system | AHRI certified value                |
| Coefficient of performance of the assumed baseline equipment (electric resistance) at -15°C [kW/kW] | $COP_{base\_min}$ | 1                                            | Assumed COP for electric resistance |
| Coefficient of performance of the new heat pump at -15°C [kW/kW]                                    | $COP_{ee\_min}$   | Specification data for each installed system | AHRI certified value                |
| Conversion factor [Btu/W·h]                                                                         | 3.412             | 3.412                                        | Convention                          |
| Conversion factor [W/kW]                                                                            | 1,000             | 1,000                                        | Convention                          |

For Green Heat, peak demand savings are only claimed for households with a fully electrically heated baseline and are nil for mainly electrically heated baselines since the billing analysis resulted in nil electrical energy savings for those homes.

For some models, the availability of a heating capacity and COP at -15°C is limited. For those models, peak demand savings are considered nil if the specification sheets indicate a cut-off temperature above -15°C, otherwise ratios are applied to the rated COP and heating capacity at 47°F to obtain values considering average performance reductions as per simulation software (DOE- 2) performance curves shared by NRCan. The two following equations are used to obtain the adjusted values.

$$COP_{ee\_min} = 53.78\% \times \text{Rated COP at } 47^{\circ}\text{F}$$

$$HC_{min} = 37.46\% \times \text{Rated Capacity at } 47^{\circ}\text{F}$$

For MHEEP, unitary peak demand savings are established by multiplying the average unitary peak demand savings per capacity obtained from the mini-split heat pump measures installed under HEA by the capacity of each system installed under MHEEP and the percentage of electrical space heating.

## Installation Rates

Installation rates for MSHPs are estimated at 100% due to their relatively high cost.

## (2) Central Air-source Heat Pumps

### Summary

Table 56 presents a summary of the values used to calculate central air-source heat pump (CASHP) savings. The detailed methodology follows.

**Table 56: Central Air-source Heat Pump Measure Summary**

| Parameter                                          | Green Heat                                                                         | HEA                                                                             | Reference                                                 |
|----------------------------------------------------|------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|-----------------------------------------------------------|
| Measure Description and Identification             |                                                                                    |                                                                                 |                                                           |
| Measure                                            | Central air-source (air-to-air and air-to-water) heat pumps rebated after purchase |                                                                                 | -                                                         |
| Baseline                                           | Electric resistance space heating                                                  |                                                                                 |                                                           |
| General Parameters                                 |                                                                                    |                                                                                 |                                                           |
| Installation Rate                                  | 100%                                                                               |                                                                                 | See details below under Installation Rates                |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for CASHPs are based on the billing analysis results of the 2017 Green Heat evaluation, which yielded savings per units of capacity of 0.101 kWh/Btu/h. The unitary savings value is then multiplied by the heating capacity of the CASHP (found in the tracking sheet) and is used to calculate an energy savings value specific to each CASHP.

## Unitary Peak Demand Savings

For CASHPs installed under Green Heat, rated heating capacity and COP at -15°C are not always available. The Evaluator looked into the specification details of CASHPs installed through Green Heat in 2022 and was able to identify those parameters for up to nine models. The average unitary peak demand savings for CASHPs were then calculated using the variables defined and listed in the equation and Table 57 below.

$$Peak\ Demand\ Savings_W = \frac{HC_{min}}{3.412} \times \left( \frac{1}{COP_{base\_min}} - \frac{1}{COP_{ee\_min}} \right)$$

**Table 57: Unitary Peak Demand Savings Values for Central Air-source Heat Pumps**

| Variable                                                                                            | Symbol                    | Green Heat | Reference                                                                                   |
|-----------------------------------------------------------------------------------------------------|---------------------------|------------|---------------------------------------------------------------------------------------------|
| Rated heating capacity of the new heat pump at outdoor air temperature of -15°C [Btu/h]             | $HC_{min}$                | 26,261     | Average specification data for 7 models in the 2022 Green Heat tracking sheet <sup>83</sup> |
| Coefficient of performance of the assumed baseline equipment (electric resistance) at -15°C [kW/kW] | $COP_{base\_min}$         | 1          | Assumed COP for electric resistance                                                         |
| Coefficient of performance of the new heat pump at -15°C [kW/kW]                                    | $COP_{ee\_min}$           | 2.076      | Average specification data for 9 models in the 2022 Green Heat tracking sheet               |
| Conversion factor [Btu/W·h]                                                                         | 3.412                     | 3.412      | Convention                                                                                  |
| Unitary Peak Demand Savings [W]                                                                     | $Peak\ Demand\ Savings_W$ | 3,989      | Calculation                                                                                 |

## Installation Rates

Installation rates for CASHPs are estimated at 100% due to their relatively high cost.

<sup>83</sup> CASHP characteristics were not updated since 2022 due to the low number of CASHPs installed in subsequent years.

### (3) Ground-source Heat Pumps

#### Summary

Table 58 presents a summary of the values used to calculate ground-source heat pump (GSHP) savings. The detailed methodology follows.

**Table 58: Ground-source Heat Pump Measure Summary**

| Parameter                                          | Green Heat                                                                                                                 | HEA                                                                                    | Reference                                                 |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|-----------------------------------------------------------|
| Measure Description and Identification             |                                                                                                                            |                                                                                        |                                                           |
| Measure                                            | Ground-source heat pumps for high-efficiency space rebated after installation (HEA) or rebated after purchase (Green Heat) |                                                                                        | -                                                         |
| Baseline                                           | Electric heating resistance, CASHP, or MSHP                                                                                |                                                                                        |                                                           |

| Interactive Effects Factor for Peak Demand Savings | 0%                                                                                                                         | 0%                                                                                     | See Subsection 2.2.1                                      |

#### Electrical Unitary Energy Savings

The electrical unitary energy savings for GSHPs in Green Heat are calculated using the variables defined and listed in the equation and Table 59 below.

$$\begin{aligned}
 \text{Energy Savings}_{kWh} &= \text{Heating Savings} + \text{Cooling Savings or Penalty} \\
 &= \left( \frac{HC}{1,000} \times \left( \frac{1}{HSPF2_{base}} - \frac{1}{COP_{ee} \times DRF \times 3.412} \right) \times FLH_{heat} \right) \\
 &\quad + \left( \frac{CC}{1,000} \times \left( \frac{1}{SEER2_{base}} \times AC - \frac{1}{EER2_{ee} \times DRF \times GSER} \right) \times FLH_{cool} \right)
 \end{aligned}$$

**Table 59: Electrical Unitary Savings Values for Ground-source Heat Pumps in Green Heat**

| Parameter                                                                        | Symbol         | Value                                                          | Reference                                                                                                                                                                       |

| Conversion factor [W/kW]                                                         | 1,000          | 1,000                                                          | Convention                                                                                                                                                                      |

<sup>84</sup> Assuming a HSPF of 3.412 for electric resistance and an average HSPF2 of 6.0 for Region V, which corresponds to the minimum for “Split system central heat pumps, other than those that are small-duct and high-velocity or space-constrained” as per the NRCAN regulation available at <https://natural-resources.canada.ca/energy-efficiency/energy-efficiency-regulations/guide-canadas-energy-efficiency-regulations/split-system-central-air-conditioners-and-heat-pumps/6895>.

<sup>85</sup> Pennsylvania Public Utility Commission (PUC), *Technical Reference Manual*, August 2019, Subsection 2.2 – HVAC.

<sup>86</sup> Assumptions based on the average efficiency values cited by NRCAN for room air conditioners (average EER of 10 divided by 0.875 and by 1.05 to convert to SEER 2), <https://www.nrcan.gc.ca/energy/publications/efficiency/residential/air-conditioning/6051> and on SEER 2 for “Split-system central air conditioners, other than those that are space-constrained or small-duct and high-velocity” for central AC, for “Split system central heat pumps, other than those that are small-duct and high-velocity or space-constrained” for heat pumps as per NRCAN regulation <https://natural-resources.canada.ca/energy-efficiency/energy-efficiency-regulations/guide-canadas-energy-efficiency-regulations/split-system-central-air-conditioners-and-heat-pumps/6895>.

<sup>87</sup> Based on the average modelled heating energy consumption of HEA participants before and after their home retrofit, including 100% electrically heated participants with no heat pumps and adjusted to take into account HOT2000 overestimation ratios from the 2018 billing analysis. The averages of each year were weighted according to the number of projects.

<sup>88</sup> Minnesota Department of Commerce Division of Energy Resources, *State of Minnesota Technical Reference Manual for Energy Conservation Improvement Programs Version 3.1*, January 2020.

## Unitary Peak Demand Savings

The unitary peak demand savings for GSHPs installed under **Green Heat** are established using the equation below. All variables from this equation are defined in Table 59. Since standard MSHPs and CASHPs are assumed to operate exclusively on the electric resistance backup in the air handler during peak periods, the value of the  $COP_{base}$  variable in the formula below is the electrical baseline value of 1 regardless of the actual baseline equipment.

$$Peak\ Demand\ Savings_W = \left( 1,000 \times HC \times \left( \frac{1}{COP_{base}} - \frac{1}{COP_{ee} \times DRF} \right) \right)$$

## Installation Rates

Installation rates for GSHPs are estimated at 100% due to their relatively high cost.

## (4) Wood and Pellet Stoves/Fireplace Inserts

### Summary

Table 60 presents a summary of the values used to calculate wood and pellet stove and fireplace insert savings. The detailed methodology follows.

**Table 60: Wood and Pellet Stove and Fireplace Insert Measure Summary**

| Parameter                                          | Green Heat                                                                                                           |                  | HEA                       | Reference                                                 |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|------------------|---------------------------|-----------------------------------------------------------|
| Measure Description and Identification             |                                                                                                                      |                  |                           |                                                           |
| Measure                                            | Wood and pellet stoves and fireplace inserts rebated after installation (HEA) or rebated after purchase (Green Heat) |                  |                           | -                                                         |
| Baseline                                           | Electrical heating or heat pump                                                                                      |                  |                           |                                                           |
| Measure Subcategory                                | Stove                                                                                                                | Fireplace insert | Stove or fireplace insert |                                                           |
| General Parameters                                 |                                                                                                                      |                  |                           |                                                           |

## Electrical Unitary Energy Savings

The electrical unitary energy savings values for wood and pellet stoves and fireplace inserts are based on the billing analysis results of the 2024 Green Heat evaluation. The values obtained are valid for homes that have an existing electric resistance system or a heat pump heating system.

Measured savings were significantly lower for fireplace inserts than for stoves in the Green Heat participant population used for the billing analysis. As a result, separate unitary energy savings for Green Heat are provided for stoves and fireplace inserts. For HEA, since the tracking sheet does not allow to make the distinction between stove and fireplace insert installations, unitary energy savings for stoves are used for both stoves and fireplace inserts.

## Unitary Peak Demand Savings

Unitary peak demand savings for wood and pellet stoves and fireplace inserts installed under Green Heat and HEA were previously based on program design data.<sup>89</sup> It was assumed that, during the peak demand period, existing ASHPs operated exclusively on the electric resistance backup in the air handler. Thus, the peak demand savings for wood and pellet stoves and fireplace inserts with ASHP baselines were identical to the peak demand savings of wood and pellet stoves and fireplace inserts with electric resistance baselines.

In light of the significant reduction in unitary energy savings resulting from the billing analysis, the assumption that the existing ASHP or electric resistance assumed the heating load during peak demand periods no longer seemed valid. The Evaluator also adjusted peak demand savings. Therefore, the peak demand savings were reduced by the ratio of electrical energy savings to the previous electrical energy savings.

For Green Heat, this was done separately for stoves and fireplace inserts. For HEA, the reduction calculated for stoves is applied to both stoves and fireplace inserts since the tracking sheet does not allow to make the distinction between stove and fireplace insert installations. These calculations are presented in the equation and Table 61 below.

$$\text{Peak Demand Savings}_W = \text{Previous Peak Demand Savings}_W \times \frac{\text{Energy Savings}_{kWh}}{\text{Previous Energy Savings}_{kWh}}$$

**Table 61: Unitary Peak Demand Savings Values for Wood or Pellet Stoves and Fireplace Inserts**

| Parameter                                                                                                                                                                                                                               | Green Heat            |                                  | HEA                                        | Reference          |

| Energy Savings [kWh]                                                                                                                                                                                                                    | 1,461                 | 232                              | 1,461                                      | 2024 DSM MA        |
| Previous Energy Savings [kWh]*                                                                                                                                                                                                          | 7,055*                |                                  |                                            | 2020-2023 DSM MA   |
| <b>Peak Demand Savings [W]</b>                                                                                                                                                                                                          | <b>828</b>            | <b>132</b>                       | <b>828</b>                                 | <b>Calculation</b> |
| *The values presented correspond to the arithmetic mean of the tracked unitary electrical energy savings for wood or pellet stoves with a heat pump or electric resistance baseline since these measures have all been merged into one. |                       |                                  |                                            |                    |

## Installation Rates

Installation rates for wood and pellet stoves are estimated at 100% due to their relatively high cost.

<sup>89</sup> Dunsy Energy Consulting, *Residential Fuel Substitution Pilot Program*, Final Report, December 2010.

## (5) Wood and Pellet Boilers and Furnaces

### Summary

Table 62 presents a summary of the values used to calculate wood and pellet boiler and furnace savings. The detailed methodology follows.

**Table 62: Wood and Pellet Boiler and Furnace Measure Summary**

| Parameter                                          | Green Heat                                                                                                   |        |           |        | HEA        |        |                                 |                                 | Reference                                                 |

## Electrical Unitary Energy Savings

The electrical unitary savings values for wood and pellet boilers and furnaces are based on HOT2000 energy models.<sup>90</sup> The baseline of the models used electric resistance heating as the primary heat source and was calibrated to account for the historical electrical consumption of participants.

For participants who have ASHPs, as their primary heating system instead of electric resistance heating, unitary savings values are calculated using the equation below.

$$Energy\ Savings_{kWh\ (base\_hp)} = Energy\ Savings_{kWh\ (base\_elec)} \times \frac{COP_{base\_elec}}{COP_{base\_hp}}$$

For HEA, the baseline heat pump COP value specified in the tracking sheet is used, while for Green Heat, the COP of a standard mini-split heat pump based on a HSPF2 Region V of 6.0 is used.<sup>91</sup> The unitary energy savings values are presented in Table 63 below.

---

<sup>90</sup> The HOT2000 energy models were developed as part of the 2013 evaluation.

<sup>91</sup> Assuming an average HSPF2 of 6.0 for Region V, which corresponds to the minimum for “Split system central heat pumps, other than those that are small-duct and high-velocity or space-constrained” as per the NRCan regulation available at <https://natural-resources.canada.ca/energy-efficiency/energy-efficiency-regulations/guide-canadas-energy-efficiency-regulations/split-system-central-air-conditioners-and-heat-pumps/6895>.

## Unitary Peak Demand Savings

For Green Heat, unitary peak demand savings are based on program design data.<sup>92</sup> It is assumed that during the peak demand period, existing ASHPs operate exclusively on the electric resistance backup in the air handler. Thus, the peak demand savings for wood and pellet boiler and furnace measures with an ASHP baseline are identical to the peak demand savings with an electric resistance baseline.

The unitary peak demand savings values are presented in Table 64 below.

**Table 64: Unitary Peak Demand Savings Values for Wood and Pellet Boilers and Furnaces**

| Parameter                       | Green Heat                                      |                                                   |                                           |                                             |
|---------------------------------|-------------------------------------------------|---------------------------------------------------|-------------------------------------------|---------------------------------------------|
|                                 | Wood Furnace or Boiler with Electrical Baseline | Pellet Furnace or Boiler with Electrical Baseline | Wood Furnace or Boiler with ASHP Baseline | Pellet Furnace or Boiler with ASHP Baseline |
| Unitary Peak Demand Savings [W] | 7,660                                           | 7,750                                             | 7,660                                     | 7,750                                       |

## Installation Rates

Installation rates for wood and pellet boilers and furnaces are estimated at 100% due to their relatively high cost.

## (6) Solar Air Heating

### Summary

Table 65 presents a summary of the values used to calculate solar air heating savings. The detailed methodology follows.

<sup>92</sup> Dunskey Energy Consulting, *Residential Fuel Substitution Pilot Program*, Final Report, December 2010.

**Table 65: Solar Air Heating Measure Summary**

| Parameter                                          | Green Heat                                           | Reference                                                                              |

## Electrical Unitary Energy Savings

The unitary savings value for solar air heating systems installed through Green Heat is calculated for each system.

## Installation Rates

Installation rates for solar air heating are estimated at 100% due to their relatively high cost.

## (7) Air Sealing Products

### Summary

Table 66 presents a summary of the values used to calculate air sealing product savings. The detailed methodology follows.

**Table 66: Air Sealing Product Measure Summary**

| Parameter                                          |                                                                            | EPI        |                            |                                |                        |            |                            |                                |                                                                                        | Reference |

## Electrical Unitary Energy Savings

The electrical unitary energy savings values are based on the results of an evaluation of a residential weatherization program conducted in Connecticut by KEMA in 2010.<sup>93</sup> Based on post-retrofit blower door tests on sampled homes, which included single-family homes as well as apartments, the KEMA evaluation report provides per-foot unitary savings values for window air sealing and door weather stripping, as well as per-unit unitary savings for foam gaskets and door sweeps. For heat pump heating systems, the savings from electric resistance are divided by 1.8, the COP of a standard mini-split heat pump based on a HSPF2 Region V of 6.0.<sup>94</sup>

Table 67 summarizes the savings for each measure included in air sealing products for electric resistance.

**Table 67: Savings Values for Air Sealing Products in Electric Resistance and Heat Pump Heated Homes**

| Measure                                                      | Electric Resistance Heated Homes | Heat Pump Heated Homes | Reference                                                    |
|--------------------------------------------------------------|----------------------------------|------------------------|--------------------------------------------------------------|
| Annual Energy Savings from Foam Gaskets [kWh/gasket]         | 9                                | 5.00                   | <u>Electric Resistance:</u><br>Connecticut TRM <sup>95</sup> |
| Annual Energy Savings from Door Sweeps [kWh/door]            | 173                              | 96.1                   |                                                              |
| Annual Energy Savings from Window Air Sealing [kWh/foot]     | 9.9                              | 5.50                   |                                                              |
| Annual Energy Savings from Door Weather Stripping [kWh/foot] | 11.5                             | 6.39                   | <u>Heat Pump:</u><br>Calculation                             |

<sup>93</sup> United Illuminating Company and Connecticut Light & Power Company, *Connecticut Program Savings Document, 15<sup>th</sup> Edition for 2019 Program Year*, March 2019.

<sup>94</sup> Assuming an average HSPF2 of 6.0 for Region V, which corresponds to the minimum for “Split system central heat pumps, other than those that are small-duct and high-velocity or space-constrained” as per the NRCan regulation available at <https://natural-resources.canada.ca/energy-efficiency/energy-efficiency-regulations/guide-canadas-energy-efficiency-regulations/split-system-central-air-conditioners-and-heat-pumps/6895>.

### Electrical Unitary Energy Savings

The electrical unitary energy savings values of the window kit measure are calculated using the equations below.

$$\begin{aligned}
 \text{Energy Savings (kWh)} &= ES_{\text{sealing}} + ES_{\text{insulation}} \\
 ES_{\text{sealing}} &= \frac{n_{\text{window}} \times p_{\text{window}} \times ESPF_{\text{tape}}}{COP} \times \frac{HDD_{NS}}{HDD_{CT}} \\
 ES_{\text{insulation}} &= \frac{HDD_{NS} \times n_{\text{window}} \times A_{\text{window}} \times 24 \times ADJ}{COP \times 3,413} \times \left( \frac{1}{R_{\text{window}}} - \frac{1}{R_{\text{window}} + R_{\text{air}}} \right)
 \end{aligned}$$

<sup>96</sup> Illinois Commerce Commission, *Illinois Statewide Technical Reference Manual for Energy Efficiency Version 12.0, Volume 3*, September 22, 2023, p. 384.

Total energy savings for this measure were calculated by combining savings from insulation and sealing; for the number of units, it was assumed that each kit could be used to cover two two-foot by three-foot windows.

The energy savings per foot of tape (ESPF) used in the second equation for sealing was taken from Connecticut's 2021 Program Savings Document;<sup>97</sup> the value was adjusted to the Nova Scotia context by using a heating degree days (HDD) ratio between Connecticut and Nova Scotia.

For the savings generated by insulation, the resistance values of the window and the added air layer due to film shrinkage ( $R_{\text{window}} + R_{\text{air}}$ ) were based on specific values provided by the 2022 Iowa Energy Efficiency Statewide Technical Reference Manual.<sup>98</sup> That TRM also provides an adjustment factor of 0.63 for wall insulation, used to account for overclaiming savings due to prescriptive engineering algorithms.

Table 70 presents the parameters used to calculate unitary energy savings for window film kits installed through EPI.

**Table 70: Electrical Unitary Savings Calculations for Window Film Kits**

## Electrical Unitary Energy Savings

For programmable thermostats, the electrical unitary energy savings are based on the results from a Hydro-Québec 2009 program evaluation of electronic thermostats in residential new construction.<sup>100</sup> In this evaluation, savings values include energy savings generated by the thermostat's accuracy and temperature setback and are established for three types of dwellings: single-family homes, duplex/triplex/ townhouses, and apartments. For MHEEP, the savings values were determined only for single-family homes since that corresponds to most of its participants, and the savings values include energy savings generated by the thermostat's accuracy and temperature setback since MHEEP only replaces analog thermostats. As for Instant Savings, savings values were determined for all three types of dwellings and the baseline was set at 50% analog thermostats and 50% electronic thermostats. As defined by the equation below, the unitary savings values are calculated through a weighted average based on the proportion of each dwelling type in Nova Scotia's residential market, as defined in the 2021 Census Profile of Statistics Canada.<sup>101</sup>

$$Energy\ Savings_{kWh} = \sum (Dwelling\ Proportion \times Total\ Savings)$$

Table 72 presents the parameters used to calculate unitary energy savings for programmable thermostats installed through Instant Savings.

| Interactive Effects Factor for Peak Demand Savings |                                                                                      |      |                                                 |      |                                                 |      |                                                                                        |

## Electrical Unitary Energy Savings

Some models of smart thermostats sold through Instant Savings or installed through EPI or MHEEP are compatible with electrical heating systems. They operate by connecting to a single baseboard, MSHP, or in-floor heating system as opposed to a central heating system. The equation below is used to calculate the unitary savings value for smart thermostats compatible with electrical heating systems and installed through Instant Savings, EPI or MHEEP.

$$Energy\ Savings_{kWh} = \frac{Heating\ Energy \times \%Savings \times FMT}{COP}$$

Since no studies specific to smart thermostats connected to electric baseboards, MSHPs, or electric in-floor heating systems were identified, the percentage of the heating load saved by thermostats is based on available studies for smart thermostats compatible with central heating systems, which have essentially the same features. Table 74 presents two billing analyses conducted for Nest smart thermostats installed on central electrical heating systems (rather than natural gas or oil heating systems). Both analyses served to assess the savings for smart thermostats installed to replace both programmable and non-programmable thermostats, which is a reasonable baseline. In both studies, heating consumption savings of 12% were evaluated for central air-source heat pumps, which is the closest heating system to electric baseboards, MSHPs, and electric in-floor heating systems among Nest compatible systems.

**Table 74: Billing Analysis Savings Results for Smart Thermostats for Electrical Heating Systems**

| Jurisdiction                                   | Measure          | Sample Size | Heating Consumption Savings |
|------------------------------------------------|------------------|-------------|-----------------------------|
| Oregon <sup>105</sup>                          | Nest thermostats | 185         | 12% (for ASHPs)             |
| Bonneville Power Administration <sup>106</sup> | Nest thermostats | 176         | 12% (for ASHPs)             |

As previously mentioned, electric baseboards, MSHPs, or electric in-floor heating systems are individually paired to a unique compatible smart thermostat. Therefore, the savings are divided by the average number of electrical heating systems within a dwelling, assuming there is one baseboard per room, one MSHP per floor, and one electric in-floor heating system per room.

<sup>107</sup> Based on the average modelled heating energy consumption of HEA participants. As for single-family homes, multiplied by the ratio of household energy intensity of Nova Scotia apartments (48.2 GJ/household) to household energy intensity of Nova Scotia single-detached homes (101.6 GJ/household). Values from Table 34: *Single Detached Secondary Energy Use and GHG Emissions by Energy Source* and Table 38: *Apartments Secondary Energy Use and GHG Emissions by Energy Source* for Nova Scotia's residential sector in Natural Resources Canada's 2021 Comprehensive Energy Use Database. Natural Resources Canada, 2021 Comprehensive Energy Use Database, [https://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/menus/trends/comprehensive/trends\\_res\\_ns.cfm](https://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/menus/trends/comprehensive/trends_res_ns.cfm).

<sup>108</sup> Based on the average modelled heating energy consumption of HEA participants before and after their home retrofit, including 100% electrically heated participants with no heat pumps and adjusted to take into account HOT2000 overestimation ratios from the 2018 billing analysis. The averages of each year were weighted according to the number of projects.

<sup>109</sup> Assuming 1 thermostat per room for electric baseboards and in-floor heating and 6.5 rooms on average based on Statistics Canada 2016 Census. For MSHP, Assuming 1 thermostat per indoor unit and 2 indoor units per home. Statistics Canada, Census Profile, 2016 Census, <https://www12.statcan.gc.ca/census-recensement/2016/dp-pd/prof/details/Page.cfm?Lang=E&Geo1=PR&Code1=12&Geo2=&Code2=&Data=Count&SearchType=Begin&SearchPR=01&B1=All> (last accessed December 3, 2019).

## Installation Rates

For Instant Savings and MHEEP, the installation rates are assumed to be 100%. For EPI, an installation rate of 84% was measured during the 2024 EPI on-site visits for smart thermostats for MSHPs. For smart thermostats controlling electric baseboards and electric in-floor heating delivered through EPI, the 100% installation rate assumption is maintained since installation rates for these types of smart thermostats were not measured during the on-site visits.

Table 76 lists the installation rate for EPI smart thermostats for MSHPs.

**Table 76: EPI Smart Thermostat for MSHP Installation Rate**

| Measure Description         | Installation Rate | Margin of Error | Reference                            |
|-----------------------------|-------------------|-----------------|--------------------------------------|
| Smart Thermostats for MSHPs | 84%               | 12.3%           | 2024 EPI evaluation (on-site visits) |

## (11) Advanced Learning Thermostat for Central Heating Systems

### Summary

Table 77 presents a summary of the values used to calculate advanced learning thermostat for central heating system savings. The detailed methodology follows.

<sup>110</sup> Assuming 1 thermostat per room for electric baseboards and in-floor heating and 4 rooms on average derived from Statistics Canada 2021 Census given the current distribution of occupied private dwellings and number of rooms. For MSHPs, assuming 1 thermostat for the entire apartment. Statistics Canada, Census Profile, 2021 Census, <https://www12.statcan.gc.ca/census-recensement/2021/dp-pd/prof/details/page.cfm?Lang=E&DGUIDlist=2021A000212&GENDERlist=1&STATISTIClist=1&HEADERlist=0&form=MG0AV3>.

<sup>111</sup> Assuming a COP of 1 for electric resistance (including baseboard and in-floor) and a COP of 1.8 for heat assuming an average HSPF2 of 6.0 for Region V, which corresponds to the minimum for "Split system central heat pumps, other than those that are small-duct and high-velocity or space-constrained" as per the NRCan regulation available at <https://natural-resources.canada.ca/energy-efficiency/energy-efficiency-regulations/guide-canadas-energy-efficiency-regulations/split-system-central-air-conditioners-and-heat-pumps/6895>.

## Electrical Unitary Energy Savings

The equation below is used to calculate the unitary savings value for learning thermostats compatible with central electrical heating systems and installed through EPI.

$$Energy\ Savings_{kWh} = \frac{Heating\ Energy \times \%Savings}{COP}$$

The billing analyses and the 12% savings presented in Table 74 are applicable to this measure. Table 78 below presents the variables used for the unitary savings calculation and the resulting value.

**Table 78: Electrical Unitary Energy Savings Calculation for Smart Thermostats for Electrical Heating Systems**

| Parameter                                               | Symbol                | Value for Central Heat Pump | Value for Electric Furnace | Reference                                               |
|---------------------------------------------------------|-----------------------|-----------------------------|----------------------------|---------------------------------------------------------|
| Average Heating Energy Consumption of a Home [kWh/year] | <i>Heating Energy</i> | 16,915                      |                            | 2021, 2022, and 2023 HEA tracking sheets <sup>112</sup> |
| Percentage of Heating Load Saved by Smart Thermostats   | <i>%Savings</i>       | 12%                         |                            | Literature review of billing analyses, see Table 74     |
| Heating System Coefficient of Performance               | <i>COP</i>            | 1.8                         | 1                          | Assumption <sup>113</sup>                               |
| <b>Unitary Energy Savings [kWh/year]</b>                | -                     | <b>1,128</b>                | <b>2,030</b>               | <b>Calculation</b>                                      |

## Installation Rates

For EPI the installation rate is assumed to be 100%.

<sup>112</sup> Based on the average modelled heating energy consumption of HEA participants before and after their home retrofit, including 100% electrically heated participants with no heat pumps and adjusted to take into account HOT2000 overestimation ratios from the 2018 billing analysis. The averages of each year were weighted according to the number of projects.

<sup>113</sup> Assuming a COP of 1 for electric resistance (electric furnace) and a COP of 1.8 for heat pumps assuming an average HSPF2 of 6.0 for Region V, which corresponds to the minimum for "Split system central heat pumps, other than those that are small-duct and high-velocity or space-constrained" as per the NRCAN regulation available at <https://natural-resources.canada.ca/energy-efficiency/energy-efficiency-regulations/guide-canadas-energy-efficiency-regulations/split-system-central-air-conditioners-and-heat-pumps/6895>.

## 2.4 Appliances

### 2.4.1 Interactive Effects

Retiring old appliances causes an increase in the heating load in the winter and a decrease in the cooling load in the summer since compressors on old appliances release significantly more waste heat than newer, more efficient models. If an inefficient appliance is retired without being replaced, interactive effects are greater.

The heating load period in Nova Scotia lasts about eight months, while the cooling load period is relatively short, lasting approximately two months. The annual total interactive effects due to the retirement or replacement of old appliances are therefore expected to be negative, pushing the savings generated by such retirements or replacements downward.

Several other factors can also affect the interactive effects of E1 appliance measures:

- › Close to all appliance measures are accounted for in E1 DSM savings and thus the focus is on electricity savings for appliances. In Nova Scotia, 25% of households use electricity as their primary heating source.<sup>114</sup> Therefore, the negative interactive effects on the heating load only affect approximately one-third of participating households.
- › A significant number of appliances targeted through E1 programs, such as refrigerators and freezers, are built into or leaned against an exterior wall. Rather than contributing to building heat loads, this results in more heat loss through the building envelope and through the appliance back wall, thereby reducing interactive effects.
- › In Nova Scotia, over one third of households (38%)<sup>115</sup> use air conditioning. For these households, positive interactive effects occur during the cooling period, which cancel a portion of the negative interactive effects.
- › Most jurisdictions that offer refrigerator and freezer programs do not consider interactive effects for those appliances.<sup>116</sup>

Considering all these factors, the interactive effects for appliances are negligible and, therefore, the interactive effects factors for energy and peak demand savings are 0%.

Table 79 summarizes the interactive effect factors established for appliances.

<sup>114</sup> Statistics Canada, *Residential Sector, Nova Scotia, Table 14: Total Households by Building Type and Energy Source*, <https://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/showTable.cfm?type=CP&sector=res&juris=ns&year=2020&rn=14&page=0>, (last accessed September 25, 2024).

<sup>115</sup> Statistics Canada, *Table 38-10-0019-01 – Air conditioners*, <https://www150.statcan.gc.ca/t1/tbl1/en/cv.action?pid=3810001901> (last accessed September 2024).

<sup>116</sup> The TRMs for California Municipal Utilities, Connecticut, Illinois, Maine, Massachusetts, Minnesota, Mid-Atlantic, New York, Northwest Power and Conservation Council, Ohio, Pennsylvania, Vermont, and Wisconsin were consulted. Only Northwest Power and Conservation Council and New York apply interactive effects factors for freezers and refrigerators (although only for new rebated appliances and not for recycled appliances).

### 2.4.2 Peak Demand Savings Factors

For most appliances, peak demand savings are calculated using the peak demand-to-energy ratios developed by Navigant in the 2016-2018 DSM Plan. These ratios were established for various product categories based on modelled system-coincident peak demand savings and electrical energy savings for a projected deployment of products. Navigant used local data to establish the ratios applicable for the 2016-2018 period. The Evaluator recommends using the same ratios during the 2020-2023 DSM cycle.

The Evaluator assumes a peak demand-to-energy ratio of zero for clotheslines, outdoor drying racks, and retired air room conditioners since these products are not likely used on cold winter days when peak conditions occur.

Table 80 summarizes the peak demand-to-energy ratios established for appliances.

**Table 80: Peak Demand-to-energy Ratios for Appliances**

| Measure                                                                          | Peak Demand-to-energy Ratio (W/kWh) | Source                                                                                                                                          |

## 2.4.3 Appliance Measures

### (1) Clotheslines and Outdoor Drying Racks

#### Summary

Table 81 presents a summary of the values used to calculate clothesline and outdoor drying rack savings. The detailed methodology follows.

**Table 81: Clothesline and Outdoor Drying Rack Measure Summary**

| Parameter                                          | Instant Savings                                        | Reference                                                                              |
|----------------------------------------------------|--------------------------------------------------------|----------------------------------------------------------------------------------------|
| Measure Description and Identification             |                                                        |                                                                                        |
| Measure Description                                | Clotheslines and outdoor drying racks rebated in store | -                                                                                      |
| Baseline                                           | Clothes being dried with a clothes dryer               |                                                                                        |
| General Parameters                                 |                                                        |                                                                                        |
| Installation Rate                                  | 100%                                                   | See details below under Installation Rates                                             |
| Effective Useful Life [years]                      | 10                                                     | See Subsection 3.2                                                                     |
| Electrical Savings Parameters                      |                                                        |                                                                                        |
| Unitary Energy Savings [kWh/year]                  | 70.6                                                   | See details below under Electrical Unitary Energy Savings                              |
| Peak Demand-to-energy Ratio [W/kWh]                | 0.000                                                  | See Subsection 2.4.2                                                                   |
| Unitary Peak Demand Savings [W]                    | 0                                                      | Calculated by multiplying the unitary savings value by the peak demand-to-energy ratio |
| Interactive Effects Factor for Energy Savings      | 0%                                                     | See Subsection 2.4.1                                                                   |
| Interactive Effects Factor for Peak Demand Savings | 0%                                                     | See Subsection 2.4.1                                                                   |

#### Electrical Unitary Energy Savings

The savings from this measure are due to avoided clothes dryer loads. The following equation is used to establish the unitary savings associated with clotheslines and outdoor drying racks.

$$\begin{aligned} \text{Energy Savings} \left[ \frac{kWh}{\text{year}} \right] &= \text{Annual Laundry Loads} \left[ \frac{\text{load}}{\text{year}} \right] \\ &\times \text{Proportion of Loads Dried on Clotheslines or Outdoor Drying Racks} [\%] \\ &\times \text{Energy Consumption per Load} \left[ \frac{kWh}{\text{load}} \right] \end{aligned}$$

Table 82 below lists the parameters and corresponding values applied in the equation above for clotheslines and outdoor drying racks installed and the resulting unitary savings values.

**Table 82: Electrical Unitary Savings Values for Clotheslines and Outdoor Drying Racks**

| Parameter                                     | Value       | Source                                                                                                                          |
|-----------------------------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------|
| Number of Laundry Loads per Year [loads/year] | 197         | Research to update this value showed that it hardly changed, so the one established in 2015 NRCan <sup>118</sup> was maintained |
| Proportion of Loads Dried on Clotheslines [%] | 16.3%       | 2011 OPA Prescriptive Measures and Assumptions List <sup>119</sup>                                                              |
| Energy Consumption per Load [kWh/load]        | 2.2         | 2011 OPA Prescriptive Measures and Assumptions List <sup>120</sup>                                                              |
| <b>Unitary Energy Savings [kWh/year]</b>      | <b>70.6</b> | <b>Calculation</b>                                                                                                              |

## Installation Rates

For Instant Savings, the installation rate is assumed to be 100% since participants have to purchase the product.

## Electrical Unitary Energy Savings

The following equations are used to determine the electrical unitary energy savings value of retired and replaced refrigerators.

$$\text{Energy Savings}_{kWh} = \text{AvgConsumptionPerSize} \times \text{AvgSize} \times \text{OAR} \times \text{PuF} - \text{NewConsumption}$$

$$\text{AvgConsumptionPerSize} = \sum (\text{ConsumptionPerSize} \times \% \text{ManufactureSplit})$$

For regular and small refrigerators retired through ARet, average annual per-cubic-foot energy consumption is calculated using 2017 metering activity results<sup>121</sup> for appliances manufactured before 2002 and the results of NRCAN data analyses for appliances manufactured in or after 2002.

Since most retired units in the category “manufactured in or after 2002” are now more recent than the most recent units used in the 2017 metering activity, unitary savings values for refrigerators manufactured in 2002 or later were established using data extracted from NRCAN EnerGuide appliance directories from 2001 to 2012.<sup>122</sup> Model numbers in the 2022 and 2023 tracking sheets were matched with EnerGuide data to extract energy consumption values.<sup>123</sup> Given retired appliances manufactured in 2002 or later are on average 15 years old, the Evaluator increased the EnerGuide energy consumption level by 27% to account for the efficiency loss due to aging based on findings from a recently published metering study.<sup>124</sup>

Average annual consumption values by manufacture-year class<sup>125,126,127</sup> were established and a weighted average was calculated based on 2024 tracking sheet proportion of units per manufacture-year class. The occupant adjustment factor is based on the metering protocol of the New York Department of Public Service<sup>128</sup> and the part-use factor is calculated based on 2022 participant survey data.<sup>129</sup>

For refrigerators replaced through HomeWarming and MHEEP, the unitary savings value is based on the average annual per-cubic-foot energy consumption of refrigerators manufactured in 1994 and earlier because eligible refrigerators correspond to this age category. It is assumed that all replaced refrigerators are primary refrigerators since it is a program component criterion and therefore no part-use factor is applied. The average size is based on data from the 2021, 2022 and 2023 tracking sheet for HomeWarming and MHEEP. The energy consumption of installed new refrigerators is calculated based on 2021, 2022 and 2023 HomeWarming and MHEEP tracking sheet data and the energy consumption rating of each model as labeled by EnerGuide retrieved using the ENERGY STAR Product Finder Tool.<sup>130</sup>

## Electrical Unitary Energy Savings

To determine the electrical unitary energy savings value of retired (ARet) and replaced (ASFH, MHEEP) freezers, the following equations are used.

$$\text{Energy Savings}_{kWh} = \text{AvgConsumptionPerSize} \times \text{AvgSize} \times \text{OAR} \times \text{PuF} - \text{NewConsumption}$$

$$\text{AvgConsumptionPerSize} = \sum(\text{ConsumptionPerSize} \times \% \text{ManufactureSplit})$$

For regular and small freezers retired through ARet, the average annual per-cubic-foot energy consumption is calculated using 2017 metering activity results<sup>131</sup> for appliances manufactured before 2002 and the results of NRCAN data analyses for appliances manufactured in or after 2002.

Since most retired units in the category “manufactured in or after 2002” are now more recent than the most recent units used in the 2017 metering activity, unitary savings values for refrigerators manufactured in 2002 or later were established using data extracted from NRCAN EnerGuide appliance directories from 2001 to 2012.<sup>132</sup> Model numbers in the 2022 and 2023 tracking sheets were matched with EnerGuide data to extract energy consumption values.<sup>133</sup> Given retired appliances manufactured in 2002 or later are on average 15 years old, the Evaluator increased the EnerGuide energy consumption level by 27% to account for the efficiency loss due to aging based on findings from a recently published metering study.<sup>134</sup>

Average annual consumption values by manufacture-year class<sup>135,136,137</sup> were established and a weighted average was calculated based on 2024 tracking sheet proportion of units per manufacture-year class. The occupant adjustment factor is based on the metering protocol of the New York Department of Public Service<sup>138</sup> and the part-use factor is calculated based on 2022 participant survey data.<sup>139</sup>

For freezers replaced through HomeWarming and MHEEP, the unitary savings value is based on the average annual per-cubic-foot energy consumption of freezers manufactured in 1994 and earlier because eligible freezers correspond to this age category. It is assumed that all replaced freezers are primary freezers since it is a program component criterion and therefore no part-use factor is applied. The average size is based on data from the 2021, 2022 and 2023 tracking sheet for HomeWarming and MHEEP. The energy consumption of installed new freezers is calculated based on 2021, 2022 and 2023 HomeWarming and MHEEP tracking sheet data and the energy consumption rating of each model as labeled by EnerGuide retrieved using the ENERGY STAR Product Finder Tool.<sup>140</sup>

| Interactive Effects Factor for Peak Demand Savings | 0%                                                    | See Subsection 2.4.1                                                                   |

### Electrical Unitary Energy Savings

The electrical unitary energy savings of retired room air conditioners are calculated using the equations below.

$$Energy\ Savings_{kWh} = \frac{Q \times HOU}{SEER \times 1,000}$$
$$SEER = EER \times RACER$$

The retired unit average capacity variable is calculated using tracking sheet data from 2021 through 2023.

The hours of operation variable is based on NRCan's EnerGuide Room Air Conditioner Directory,<sup>141</sup> which provides local data for four cities in Nova Scotia, namely Halifax, Yarmouth, Sydney, and Greenwood, and is calculated by taking into account the proportion of those participants who retired a room air conditioner in each of the regions of these four cities in 2022. The participants' postal codes recorded in the ARet tracking sheet were used to determine their locations. The following formula was used to calculate the weighted average hours of operation across the province.

$$\begin{aligned} \text{Annual Hours of Operation} \left[ \frac{\text{hr}}{\text{yr}} \right] &= (\%_{\text{people}} \times \text{HOU})_{\text{Halifax}} + (\%_{\text{people}} \times \text{HOU})_{\text{Yarmouth}} + (\%_{\text{people}} \times \text{HOU})_{\text{Sydney}} \\ &+ (\%_{\text{people}} \times \text{HOU})_{\text{Greenwood}} \end{aligned}$$

It is assumed that most air conditioners retired through ARet meet the energy efficiency ratio (EER) of 9.5 as per Natural Resources Canada values for stock room air conditioning units in 2006<sup>142</sup> since 54% of the air conditioning units retired through ARet between 2021 and 2023 were manufactured from 2003 through 2009. To account for seasonal temperature changes, the EER of 10.5 should be multiplied by a factor of 1.11 in accordance with the Ecox Technical Information Bulletin on SEER.<sup>143</sup>

Table 88 below presents the parameters of the above equations as well as the unitary savings calculations for the room air conditioner retirement measure.

**Table 88: Electrical Unitary Savings Values for Room Air Conditioner Retirement**

| Parameter                                                                    | Symbol                                   | ARet       | Reference                                           |

### Electrical Unitary Energy Savings

For both ARet and Instant Savings, dehumidifier electrical unitary energy savings are calculated using the equation below.

$$Energy\ Savings_{kWh} = AWRC \times AOD \times \left( \frac{1}{EF_{base}} - \frac{1}{EF_{new}} \right)$$

<sup>146</sup> While dehumidifier replacements are offered and reported under ASFH and MHEEP, this measure is administered by ARet.

For ARet, the baseline energy factor is based on the 2011 Ontario Power Authority (OPA) Prescriptive Measures and Assumptions report.<sup>147</sup> The new energy factor is calculated using ARet tracking sheet data from 2021 through 2023. While ARet drop-off events offer an opportunity to retire a dehumidifier without necessarily replacing it, the Evaluator assumed that participants replaced their unit since it is unlikely that a home stopped needing dehumidification.

For Instant Savings, the base energy factor corresponds to the average CEF of the non-ENERGY STAR models available in Canada listed by NRCAN.<sup>148</sup> The new energy factor is based on the 2024 Instant Savings tracking sheet and the ENERGY STAR guidelines for dehumidifiers.

For both program components, the average water removal capacity and the average operating days are based on the 2011 OPA Prescriptive Measures and Assumptions report.

Table 90 below presents the parameters of the above equations as well as the unitary savings calculations for the dehumidifier replacement and ENERGY STAR certified dehumidifier measures.

**Table 90: Electrical Unitary Savings Values for Dehumidifier Replacements or Retirements/ ENERGY STAR Certified Dehumidifiers**

| Parameter                                                           | Symbol                 | ARet, ASFH, MHEEP |      | Instant Savings                                                                                                                              |

| Interactive Effects Factor for Peak Demand Savings | 0%                                                    | See Subsection 2.4.1                                                                   |

### Electrical Unitary Energy Savings

The electrical unitary energy savings of the ENERGY STAR certified clothes dryer measure are calculated using the equations below.

$$Energy\ Savings_{kWh} = ADL \times ALW \times \left( \frac{1}{CEF_{base}} - \frac{1}{CEF_{new}} \right)$$

The average number of dried loads (ADL) was calculated from the NRCAN 2015 Survey of Household Energy Use that contained data on the number of loads per province or region such as the Atlantic region.

The combined energy factor (CEF) of the new units is based on the weighted average CEF of the 10 most installed models in 2024.

The CEF of the base unit replaced through Instant Savings corresponds to the average CEF of the non-ENERGY STAR models available in Canada listed by NRCAN.<sup>149</sup>

<sup>149</sup> Natural Resources Canada, Search: Clothes dryers| Energy Efficiency Ratings. Available at: <https://oee.nrcan.gc.ca/pml-imp/index.cfm?action=app.search-recherche&appliance=CLOTHESDRYERS> (last accessed September 25, 2024).

Table 92 below presents the parameters of the above equations as well as the unitary savings calculations for the ENERGY STAR Certified clothes dryer measure.

## Electrical Unitary Energy Savings

For efficient clothes washers, the electrical unitary savings value is determined by comparing baseline and efficient clothes washer annual energy consumption values, adjusted to consider the proportion of electrically heated hot water used by the appliance.

### Energy Consumption Calculation

First, the energy consumption values of both baseline and efficient clothes washers are determined using the following equation.

$$\text{Clothes Washer Energy Consumption [kWh]} = \frac{\text{Number of Loads} \left[ \frac{\text{Loads}}{\text{Year}} \right] * \text{Capacity[L]}}{\text{IMEF} \left[ \frac{\text{L}}{\text{kWh}} \right]}$$

Table 94 below lists the parameters and corresponding values applied in the equations above for baseline and efficient clothes washers and their resulting energy consumption.

**Table 94: Clothes Washer Energy Consumption**

| Parameter                                              | Symbol                                   | Value for Baseline Clothes Washer | Value for Efficient Clothes Washer | Reference                                                                                                                                                                                                                              |
|--------------------------------------------------------|------------------------------------------|-----------------------------------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Water Heating Adjustment

Both energy consumption values do not take into account the proportion of hot water for clothes washers produced with electricity in Nova Scotia, nor the use of cold water for washing. Therefore, the energy consumption of both baseline and efficient clothes washers is broken down for each stage of the washing process, as presented in Table 95, to apply correction factors separately at each stage.

**Table 95: Energy Consumption Breakdown for Baseline and Efficient Clothes Washers**

| Energy Consumption Breakdown for Clothes Washers | Proportion of Overall Consumption <sup>155</sup> | Baseline Clothes Washer Electricity Consumption (kWh/year) | Efficient Clothes Washer Electricity Consumption (kWh/year) |
|--------------------------------------------------|--------------------------------------------------|------------------------------------------------------------|-------------------------------------------------------------|
| Water Heating System                             | 24.8%                                            | 122                                                        | 83                                                          |
| Clothes Dryer                                    | 68.1%                                            | 335                                                        | 228                                                         |
| Clothes Washer Drum                              | 7.1%                                             | 35                                                         | 24                                                          |
| Total                                            | 100.0%                                           | 492                                                        | 335                                                         |

To estimate the savings attributable to water heating system energy consumption, the percentage of electrically heated water is calculated, as presented in Table 96 below. The proportion of electrical DHW tanks in Nova Scotia is used to calculate the overall proportion of electrically heated water for both baseline and efficient clothes washers. The proportion of electrical DHW tanks in Nova Scotia is based on participant data collected in the 2022 and 2023 EPI tracking sheets.<sup>156,157</sup>

**Table 96: Water Heating Sources for Clothes Washers**

| DHW Tank Type  | Proportion |
|----------------|------------|
| Electrical     | 76%        |
| Non-electrical | 24%        |

For water heating consumption, an adjustment factor for cold water washing is applied. Thus, to account for the usage of cold water for washing, the water heating energy consumption value is multiplied by a factor of 0.67, which is based on a survey conducted by Hydro-Québec that found that 67% of washes are done in heated water.<sup>158</sup>

## Adjusted Energy Consumption

Table 97 and Table 98 present the calculations of total electricity consumption for baseline and efficient clothes washers respectively.

<sup>155</sup> Ad Hoc Recherche, *Rapport d'évaluation, Programme : Produits Mieux Consommer – Électroménagers Energy Star (Années 2008 et 2009)*, p. 18.

<sup>156</sup> The proportions of electric water heating published by NRCAN are not consistent and significantly lower than the value obtained from EPI participants. Therefore, the proportion of electrical water heating is based on EPI tracking sheet data.

<sup>157</sup> Given the change in the EPI program in 2021, the data for the proportion of electric water heating didn't reflect what was previously observed. Therefore, data from only the 2022 and 2023 EPI tracking sheets were used.

<sup>158</sup> Ad Hoc Recherche, *Rapport d'évaluation, Programme : Produits Mieux Consommer – Électroménagers Energy Star (Années 2008 et 2009)*, p. 19.

**Table 97: Electricity Consumption for Baseline Clothes Washers**

| Energy Consumption Component | Energy Consumption (kWh/year) | Adjustment Factor for Electrical Water Heating | Adjustment Factor for Cold Water Usage | Adjusted Energy Consumption (kWh/year) |
|------------------------------|-------------------------------|------------------------------------------------|----------------------------------------|----------------------------------------|
| Water Heating System         | 122                           | 0.76                                           | 0.67                                   | 62                                     |
| Internal Clothes Dryer       | 335                           | -                                              | -                                      | 335                                    |
| Washing Machine Drum         | 35                            | -                                              | -                                      | 35                                     |
| Total                        | 492                           | -                                              | -                                      | 432                                    |

**Table 98: Electricity Consumption for Efficient Clothes Washers**

| Energy Consumption Component | Energy Consumption (kWh/year) | Adjustment Factor for Electrical Water Heating | Adjustment Factor for Cold Water Usage | Adjusted Electricity Consumption (kWh/year) |
|------------------------------|-------------------------------|------------------------------------------------|----------------------------------------|---------------------------------------------|
| Water Heating System         | 83                            | 0.76                                           | 0.67                                   | 42                                          |
| Internal Clothes Dryer       | 228                           | -                                              | -                                      | 228                                         |
| Washing Machine Drum         | 24                            | -                                              | -                                      | 24                                          |
| Total                        | 335                           | -                                              | -                                      | 294                                         |

Therefore, the unitary energy savings value is established using the energy consumption between baseline and efficient clothes washers, as presented in Table 99.

**Table 99: Electrical Unitary Savings Value for Clothes Washer**

| Parameters                                                         | Value |
|--------------------------------------------------------------------|-------|
| Adjusted Energy Consumption of Baseline Clothes Washer [kWh/year]  | 432   |
| Adjusted Energy Consumption of Efficient Clothes Washer [kWh/year] | 294   |
| Unitary Energy Savings [kWh/year]                                  | 138   |

## Installation Rates

The installation rate is assumed to be 100%.

## (8) Efficient Washer-Dryer Combination Units

### Summary

Table 100 presents a summary of the values used to calculate efficient washer-dryer combination unit savings. The detailed methodology follows.

**Table 100: Efficient Washer-Dryer Combination Units**

| Parameter                                          | Instant Savings                                             | Reference                                                                              |

### Electrical Unitary Energy Savings

For efficient washer-dryer combination units, the current models available through the program consist of a dryer and a washer with separate drums that operate separately. Therefore, the energy savings are calculated by summing the savings obtained using the same methodology as for efficient dryers (see Subsection 1.1.1(6)) and clothes washers (see Subsection 1.1.1(7)).

The electrical unitary energy savings of efficient clothes dryers are calculated using the equations below.

$$Energy\ Savings_{kWh} = ADL \times ALW \times (1/CEF_{base} - 1/(CEF_{new}))$$

The average number of dried loads (ADL) was calculated from the NRCan 2015 Survey of Household Energy Use that contained data on the number of loads per province or region such as the Atlantic region. The combined energy factor (CEF) of the new units is based on the weighted average CEF of the 10 most installed models in 2024. The CEF of the base unit replaced through Instant Savings corresponds to the average CEF of the non-ENERGY STAR models available in Canada listed by NRCan.

Table 101 below presents the parameters of the above equations as well as the unitary savings calculations for the clothes dryer replacement measure.

**Table 101: Electrical Unitary Savings Values for the Efficient Clothes Dryer Component of Efficient Washer-Dryer Combination Units**

| Parameter                                         | Symbol                  | Instant Savings | Source                                                                      |
|---------------------------------------------------|-------------------------|-----------------|-----------------------------------------------------------------------------|
| Average Dried Loads per Year [load/year]          | $ADL$                   | 197             | 2015 NRCan <sup>159</sup>                                                   |
| Average Load Weight [lbs/load]                    | $ALW$                   | 8.45            | 2019 PUC TRM <sup>160</sup>                                                 |
| Combined Energy Factor of New Unit [lbs/kWh]      | $CEF_{new}$             | 3.92            | 2024 tracking sheet                                                         |
| Combined Energy Factor of Baseline Unit [lbs/kWh] | $CEF_{base}$            | 3.72            | Average of non-ENERGY STAR models available in Canada, NRCan <sup>161</sup> |
| Unitary Energy Savings [kWh/year]                 | $Energy\ Savings_{kWh}$ | 22.8            | Calculation                                                                 |

For efficient clothes washers, the electrical unitary savings value is determined by comparing baseline and efficient clothes washer annual energy consumption values adjusted to consider the proportion of electrically heated hot water used by the appliance.

First, the energy consumption values of both baseline and efficient clothes washers are determined using the following equation.

$$Clothes\ Washer\ Energy\ Consumption\ [kWh] = \frac{Number\ of\ Loads\ \left[\frac{Loads}{Year}\right] * Capacity[L]}{IMEF\ \left[\frac{L}{kWh}\right]}$$

Table 102 below lists the parameters and corresponding values applied in the equations above for baseline and efficient clothes washers and their resulting energy consumption.

**Table 102: Clothes Washer Energy Consumption**

| Parameter                                              | Value for Baseline Clothes Washer | Value for Efficient Clothes Washer | Source                                                                                                                                                                  |
|--------------------------------------------------------|-----------------------------------|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Number of Loads [Loads/Year]                           | 218                               |                                    | 2015 NRCan <sup>162</sup>                                                                                                                                               |
| Capacity [L]                                           | 127                               |                                    | Weighted average capacity based on rebated models in 2024 and ENERGY STAR Certified Clothes Washers database <sup>163</sup>                                             |
| Integrated Modified Energy Factor (IMEF) [L/kWh/cycle] | 58.6                              | 82.4                               | <b>Baseline:</b> NRCan <sup>164</sup><br><b>Efficient:</b> Weighted average capacity based on rebated models in 2024 and ENERGY STAR Certified Clothes Washers database |
| Clothes Washer Energy Consumption [kWh/year]           | 473                               | 336                                | Calculation                                                                                                                                                             |

Both energy consumption values do not consider the proportion of hot water for clothes washers produced with electricity in Nova Scotia or the use of cold water for washing. Therefore, the energy consumption of both baseline and efficient clothes washers is broken down for each stage of the washing process, as presented in Table 103, to apply correction factors separately at each stage.

**Table 103: Energy Consumption Breakdown for Baseline and Efficient Clothes Washers**

| Energy Consumption Breakdown for Clothes Washers | Proportion of Overall Consumption <sup>165</sup> | Baseline Clothes Washer Electricity Consumption (kWh/year) | Efficient Clothes Washer Electricity Consumption (kWh/year) |
|--------------------------------------------------|--------------------------------------------------|------------------------------------------------------------|-------------------------------------------------------------|
| Water Heating System                             | 24.8%                                            | 117                                                        | 83                                                          |
| Clothes Dryer                                    | 68.1%                                            | 322                                                        | 229                                                         |
| Clothes Washer Drum                              | 7.1%                                             | 34                                                         | 24                                                          |
| Total                                            | 100.0%                                           | 473                                                        | 336                                                         |

To estimate the savings attributable to water heating system energy consumption, the percentage of electrically heated water is calculated as presented in Table 104 below. The proportion of electrical DHW tanks in Nova Scotia is used to calculate the overall proportion of electrically heated water for both baseline and efficient clothes washers. The proportion of electrical DHW tanks in Nova Scotia is based on participant data collected in the 2022 and 2023 EPI tracking sheets.<sup>166,167</sup>

<sup>162</sup> NRCan, 2015 Survey of Household Energy Use, Table 10.6. Calculated average annual washed loads for Atlantic, assuming 100 days of summer and 265 days of winter. Available at: <https://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/showTable.cfm?type=SH&sector=aaa&juris=ca&year=2015&rn=38&page=1> (last accessed September 13, 2024).

<sup>163</sup> ENERGY STAR, *ENERGY STAR Certified Residential Clothes Washers*, <https://www.energystar.gov/productfinder/product/certified-clothes-washers/> (last accessed December 21, 2018).

<sup>164</sup> Natural Resources Canada, *Search: Clothes Washers | Energy Efficiency Ratings*, <http://oee.nrcan.gc.ca/pml-imp/index.cfm?action=app.search-recherche&appliance=CLOTHESWASHERS> (last accessed September 13, 2024).

<sup>165</sup> Ad Hoc Recherche, *Rapport d'évaluation, Programme : Produits Mieux Consommer – Électroménagers Energy Star (Années 2008 et 2009)*, p. 18.

<sup>166</sup> The proportions of electric water heating published by NRCan are not consistent and significantly lower than the value obtained from EPI participants. Therefore, the proportion of electrical water heating is based on EPI tracking sheet data.

<sup>167</sup> Given the change in the EPI program in 2021, the data for the proportion of electric water heating didn't reflect what was previously observed. Therefore, data from only the 2022 and 2023 EPI tracking sheets were used.

**Table 104: Water Heating Sources for Clothes Washers**

| DHW Tank Type  | Proportion |
|----------------|------------|
| Electrical     | 76%        |
| Non-electrical | 24%        |

For water heating consumption, an adjustment factor for cold water washing is applied. Thus, to account for the usage of cold water for washing, the water heating energy consumption value is multiplied by a factor of 0.67, which is based on a survey conducted by Hydro-Québec that found that 67% of washes are done using heated water.<sup>168</sup>

Table 105 and Table 106 present the calculations of total electricity consumption for baseline and efficient clothes washers respectively.

**Table 105: Electricity Consumption for Baseline Clothes Washers**

| Energy Consumption Component | Energy Consumption (kWh/year) | Adjustment Factor for Electrical Water Heating | Adjustment Factor for Cold Water Usage | Adjusted Energy Consumption (kWh/year) |
|------------------------------|-------------------------------|------------------------------------------------|----------------------------------------|----------------------------------------|
| Water Heating System         | 117                           | 0.76                                           | 0.67                                   | 60                                     |

| Total                        | 473                           | -                                              | -                                      | 416                                    |

**Table 106: Electricity Consumption for Efficient Clothes Washers**

| Energy Consumption Component | Energy Consumption (kWh/year) | Adjustment Factor for Electrical Water Heating | Adjustment Factor for Cold Water Usage | Adjusted Electricity Consumption (kWh/year) |
|------------------------------|-------------------------------|------------------------------------------------|----------------------------------------|---------------------------------------------|
| Water Heating System         | 83                            | 0.76                                           | 0.67                                   | 42                                          |
| Internal Clothes Dryer       | 229                           | -                                              | -                                      | 229                                         |
| Washing Machine Drum         | 24                            | -                                              | -                                      | 24                                          |
| Total                        | 336                           | -                                              | -                                      | 295                                         |

The unitary energy savings value is established using the difference between the energy consumption of baseline and efficient clothes washers as presented in Table 107.

**Table 107: Electrical Unitary Savings Value for the Clothes Washer Component of Efficient Washer-Dryer Combination Units**

| Parameters                                                         | Value |
|--------------------------------------------------------------------|-------|
| Adjusted Energy Consumption of Baseline Clothes Washer [kWh/year]  | 416   |
| Adjusted Energy Consumption of Efficient Clothes Washer [kWh/year] | 295   |
| Unitary Energy Savings [kWh/year]                                  | 121   |

<sup>168</sup> Ad Hoc Recherche, *Rapport d'évaluation, Programme : Produits Mieux Consommer – Électroménagers Energy Star (Années 2008 et 2009)*, p. 19.

Summing the unitary energy savings of 22.8 kWh and 121 kWh for efficient clothes dryers and washers respectively resulted in unitary energy savings of 144 kWh for efficient washer-dryer combination units.

## Installation Rates

The installation rate is assumed to be 100%.

## (9) ENERGY STAR Certified Room Air Purifiers

### Summary

Table 108 presents a summary of the values used to calculate ENERGY STAR certified room air purifier savings. The detailed methodology follows.

**Table 108: ENERGY STAR Certified Room Air Purifier Measure Summary**

| Parameter                                          | Instant Savings                                            | Reference                                                                              |

## Electrical Unitary Energy Savings

The electrical unitary energy savings value is determined by using the following equation for ENERGY STAR certified room air purifiers.

$$\begin{aligned} \text{Energy Savings} \left[ \frac{kWh}{year} \right] &= \left[ CADR[cfm] \times \left( \frac{1}{EF_{base}} - \frac{1}{EF_{eff}} \right) \left[ \frac{W}{cfm} \right] \times HOU \left[ \frac{hours}{year} \right] \right. \\ &\quad \left. + (SBP_{base} - SBP_{eff})[W] \times (8,760 - HOU) \left[ \frac{hours}{year} \right] \right] \times \frac{1 kW}{1,000 W} \end{aligned}$$

Table 109 below lists the parameters and corresponding values applied in the equation above and the resulting unitary savings values. Most values are based on the 10 most sold models under Instant Savings in 2024, which represent 57% of air purifier sales under the program component. Other values are based on the Savings Calculator for ENERGY STAR Qualified Appliances since the Canadian government currently has no minimum requirements for room air purifiers.

**Table 109: Electrical Unitary Savings Values for ENERGY STAR Certified Room Air Purifiers**

| Parameter                             | Symbol                 | Instant Savings | Reference                                                              |
|---------------------------------------|------------------------|-----------------|------------------------------------------------------------------------|
| Clean Air Delivery Rate [cfm]         | $CADR$                 | 172             | Weighted average of the 10 most sold models in the 2024 tracking sheet |
| Efficiency for Baseline Unit [cfm/W]  | $EF_{base}$            | 1.00            | Savings Calculator for ENERGY STAR Qualified Appliances <sup>169</sup> |
| Efficiency for Efficient Unit [cfm/W] | $EF_{eff}$             | 4.24            | Weighted average of the 10 most sold models in the 2024 tracking sheet |
| Annual Operating Hours [hours/year]   | $HOU$                  | 5,840           | Savings Calculator for ENERGY STAR Qualified Appliances                |
| Standby Power for Baseline Unit [W]   | $SBP_{base}$           | 1               | Savings Calculator for ENERGY STAR Qualified Appliances                |
| Standby Power for Efficient Unit [W]  | $SBP_{eff}$            | 0.73            | Weighted average of the 10 most sold models in the 2024 tracking sheet |
| Unitary Energy Savings [kWh/year]     | $Energy Savings_{kWh}$ | 768             | Calculation                                                            |

## Installation Rates

The installation rate is assumed to be 100%.

## (10) ENERGY STAR Certified Dishwashers

### Summary

Table 110 below presents a summary of the values used to calculate ENERGY STAR certified dishwasher savings. The detailed methodology follows.

**Table 110: ENERGY STAR Certified Dishwasher Measure Summary**

| Parameter                                          | Instant Savings                                                                | Reference                                                                              |
|----------------------------------------------------|--------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Measure Description and Identification             |                                                                                |                                                                                        |
| Measure                                            | ENERGY STAR certified dishwashers that use less than 250 kWh, rebated in store | -                                                                                      |
| Baseline                                           | New non-ENERGY Star certified dishwashers                                      |                                                                                        |
| General Parameters                                 |                                                                                |                                                                                        |
| Installation Rate                                  | 100%                                                                           | See details below under Installation Rates                                             |
| Effective Useful Life [years]                      | 11                                                                             | See Subsection 3.2                                                                     |
| Electrical Savings Parameters                      |                                                                                |                                                                                        |
| Unitary Energy Savings [kWh/year]                  | 15.2                                                                           | See details below under Electrical Unitary Energy Savings                              |
| Peak Demand-to-energy Ratio [W/kWh]                | 0.0915                                                                         | See Subsection 2.4.2                                                                   |
| Unitary Peak Demand Savings [W]                    | 1.39                                                                           | Calculated by multiplying the unitary savings value by the peak demand-to-energy ratio |
| Interactive Effects Factor for Energy Savings      | 0%                                                                             | See Subsection 2.4.1                                                                   |
| Interactive Effects Factor for Peak Demand Savings | 0%                                                                             | See Subsection 2.4.1                                                                   |

### Electrical Unitary Energy Savings

The electrical unitary energy savings value is determined by using the following equation for ENERGY STAR certified dishwashers.

$$\begin{aligned}
 \text{Energy Savings} \left[ \frac{\text{kWh}}{\text{year}} \right] &= \left( \text{Consumption}_{\text{base}} - \text{Consumption}_{\text{eff}} \right) \times \left( (\% \text{Operation} + (\% \text{Water Heating} \times \% \text{Electric})) \right) \\
 &\times \frac{\text{Nb Loads}}{\text{Nb Loads Standard}}
 \end{aligned}$$

Table 111 lists the parameters and corresponding values applied in the equation above and the resulting unitary savings values. The baseline corresponds to all non-ENERGY STAR certified models available in Canada.

**Table 111: Electrical Unitary Savings Values for ENERGY STAR Certified Dishwashers**

| Parameter                                                               | Symbol                      | Instant Savings | Source                                                                                                                                   |
|-------------------------------------------------------------------------|-----------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------|

### Electrical Unitary Energy Savings

The electrical unitary energy savings for humidity sensor for bathroom exhaust fan are calculated using the variables defined and listed in the equation and Table 113 below.

$$Energy Savings_{fan} \left[ \frac{kWh}{year} \right] = \% Savings \times \left( HOU_{fan} \times CFM \left[ \frac{ft^3}{min} \right] \times \frac{1}{\eta_{fan}} \right)$$

$$Energy Savings_{heating} =$$

$$= \times CFM \left[ \frac{ft^3}{min} \right] \times \left( \left[ 0.028317 \frac{m^3}{ft^3} \right] \times \rho \left[ \frac{kg}{m^3} \right] \times C_p \left[ \frac{J}{kg \cdot ^\circ C} \right] \times \left[ \frac{1 W \cdot sec}{1 J} \right] \times \left[ \frac{1 min}{60 sec} \right] \times \left[ \frac{1 kW}{1,000 W} \right] \right) \times HOU_{heating} \times \Delta T \times \% Savings$$

The fan energy savings are shown in Table 113. These are the savings from the lowered fan usage due to the humidity sensor.

**Table 113: Electrical Savings Values for Humidity Sensors for Bathroom Exhaust Fans**

| Parameter                               | Symbol                    | EPI  | Reference                                                                                                                                                                                                                                 |

| Fan Exhaust Rate [CFM]                  | CFM                       | 99.1 | Weighted average from ENERGY STAR compliant model list and 2021 tracking sheet using the ENERGY STAR bathroom fan measure available in Instant Savings at the time. This was used as a proxy for the size of fan that consumers purchased |
| Annual Fan Operating Hours [hours/year] | $HOU_{fan}$               | 850  | Vermont TRM, 2023 <sup>177</sup>                                                                                                                                                                                                          |
| Fan Energy Savings [kWh/year]           | Energy Savings [kWh/year] | 12.0 | Calculation                                                                                                                                                                                                                               |

The energy savings per energy source is shown in Table 114, and the unitary energy savings are shown in Table 115. These are the savings on the electric heating system due to lower air infiltration. Excluded from the tables is the percentage of homes heated with non-electrical heating systems, since those would not generate electrical savings.

## Installation Rates

Installation rates for humidity sensors for bathroom exhaust fan are estimated at 100%.

<sup>178</sup> Assuming a COP of 1 for electric resistance (including baseboard and in-floor) and a COP of 1.8 for heat assuming an average HSPF2 of 6.0 for Region V, which corresponds to the minimum for “Split system central heat pumps, other than those that are small-duct and high-velocity or space-constrained” as per the NRCAN regulation available at <https://natural-resources.canada.ca/energy-efficiency/energy-efficiency-regulations/guide-canadas-energy-efficiency-regulations/split-system-central-air-conditioners-and-heat-pumps/6895>.

<sup>179</sup> Assuming a COP of 1 for electric resistance (including baseboard and in-floor) and a COP of 1.8 for heat assuming an average HSPF2 of 6.0 for Region V, which corresponds to the minimum for “Split system central heat pumps, other than those that are small-duct and high-velocity or space-constrained” as per the NRCAN regulation available at <https://natural-resources.canada.ca/energy-efficiency/energy-efficiency-regulations/guide-canadas-energy-efficiency-regulations/split-system-central-air-conditioners-and-heat-pumps/6895>.

## 2.5 Plug Load Controls

### 2.5.1 Interactive Effects

No interactive effects factors are calculated for power bars and outdoor devices because they are assumed to be negligible.

Table 116 summarizes the interactive effects factors for plug load control measures.

**Table 116: Interactive Effects Factors for Plug Load Control Measures**

| Measure                                          | Interactive Effects Factor for Energy Savings | Interactive Effects Factor for Peak Demand Savings | Reference  |
|--------------------------------------------------|-----------------------------------------------|----------------------------------------------------|------------|
| Smart Power Controller for Audiovisual Equipment | 0%                                            | 0%                                                 | Assumption |
| Power Bar with Integrated Timer                  |                                               |                                                    |            |
| Heavy-duty Outdoor Timer                         |                                               |                                                    |            |
| ENERGY STAR Certified Pool Pump                  |                                               |                                                    |            |

### 2.5.2 Peak Demand Savings Factors

For most plug load control measures, peak demand savings are calculated using the peak demand-to-energy ratios developed by Navigant in the 2016-2018 DSM Plan. These ratios were established for various product categories based on modelled system-coincident peak demand savings and electrical energy savings for a projected deployment of products. Navigant used local data to establish the ratios applicable for the 2016-2018 period. The Evaluator recommends using the same ratios during the 2020-2023 DSM cycle.

As for ENERGY STAR certified variable speed pool pumps, the Evaluator assumes a peak demand-to-energy ratio of zero since these products are not likely used on cold winter days when peak conditions occur.

Table 117 summarizes the peak demand-to-energy ratios established for each plug load control measure.

**Table 117: Peak Demand-to-energy Ratios for Plug Load Control Measures**

| Measure                                          | Peak Demand-to-energy Ratio (W/kWh) | Source                                              |
|--------------------------------------------------|-------------------------------------|-----------------------------------------------------|
| Smart Power Controller for Audiovisual Equipment | 0.000                               | RES-Plug Load Controls, Navigant 2016-2018 DSM Plan |

## 2.5.3 Plug Load Control Measures

### (1) Smart Power Controllers for Audiovisual Equipment

#### Summary

Table 118 presents a summary of the values used to calculate smart power controller for audiovisual equipment savings. The detailed methodology follows.

**Table 118: Smart Power Controllers for Audiovisual Equipment Measure Summary**

| Parameter                                          | EPI                                                                                                                    | Instant Savings    | Reference                                                                              |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|--------------------|----------------------------------------------------------------------------------------|
| Measure Description and Identification             |                                                                                                                        |                    |                                                                                        |
| Measure                                            | Smart power controllers for audiovisual equipment with direct installation (EPI) or rebated in store (Instant Savings) |                    | -                                                                                      |
| Baseline                                           | Non-smart power controllers                                                                                            |                    |                                                                                        |
| Measure Subcategory                                | Tier 2 power strip                                                                                                     | Tier 1 power strip |                                                                                        |
| General Parameters                                 |                                                                                                                        |                    |                                                                                        |
| Installation Rate                                  | 100%                                                                                                                   | 86%                | See details below under Installation Rates                                             |
| Effective Useful Life [years]                      | 4                                                                                                                      |                    | See Subsection 3.2                                                                     |
| Electrical Savings Parameters                      |                                                                                                                        |                    |                                                                                        |
| Unitary Energy Savings [kWh/year]                  | 207                                                                                                                    | 105                | See details below under Electrical Unitary Energy Savings                              |

| Unitary Peak Demand Savings [W]                    | 0.00                                                                                                                   | 0.00               | Calculated by multiplying the unitary savings value by the peak demand-to-energy ratio |
| Interactive Effects Factor for Energy Savings      | 0%                                                                                                                     |                    | See Subsection 2.5.1                                                                   |
| Interactive Effects Factor for Peak Demand Savings | 0%                                                                                                                     |                    | See Subsection 2.5.1                                                                   |

#### Electrical Unitary Energy Savings

Smart power bars rebated under EPI are classified as Tier 2, while those rebated under Instant Savings are classified as Tier 1. Tier 1 smart power bars have a master outlet that switches off other outlets when the master device is turned off. Tier 2 smart power bars have the same functionality as Tier 1 yet will additionally switch devices off when they are not used. A sensor will sense the engagement of the user. Based on those differences, a specific electrical unitary savings is defined for each program component.

The electrical unitary savings energy value associated with the use of Tier 1 and Tier 2 smart power controllers for audiovisual equipment installed under EPI is based on a metering study, published in 2019, of 133 households across Massachusetts.<sup>181</sup> This study represents the most up-to-date research using treatment and control sites with a significantly large sample size.

Table 119 presents the annual unitary savings values for EPI and for Instant Savings and the source of those values.

**Table 119: Electrical Unitary Savings Values for Smart Power Controller Audiovisual Equipment**

| Parameter                         | EPI | Instant Savings | Reference                      |
|-----------------------------------|-----|-----------------|--------------------------------|
| Unitary Energy Savings [kWh/year] | 207 | 105             | NMR Group, 2019 <sup>182</sup> |

## Installation Rates

For EPI, Table 120 lists the installation rate for smart power controllers for audiovisual equipment.

**Table 120: EPI Smart Power Controller for Audiovisual Equipment Installation Rate**

| Installation Rate | Margin of Error | Reference                              |
|-------------------|-----------------|----------------------------------------|
| 100%              | 0.0%            | 2024 EPI on-site visits <sup>183</sup> |

For Instant Savings, the installation rate is 86% is based on the impact evaluation<sup>184</sup> done in parallel to the 2019 Massachusetts metering study.

<sup>181</sup> NMR Group Inc., *RLPNC 17-3: Advanced Power Strip Metering Study*, March 18, 2019.

<sup>182</sup> Ibid.

<sup>183</sup> The installation rate was not updated through the 2021 EPI site visits since this measure is no longer offered in EPI.

<sup>184</sup> NMR Group Inc., *RLPNC 17-4 and 17-5: Products Impact Evaluation of In-service and Short-Term Retention Rates Study*, October 5, 2018.

## (2) Power Bars with Integrated Timers

### Summary

Table 121 presents a summary of the values used to calculate power bar with integrated timer savings. The detailed methodology follows.

**Table 121: Power Bar with Integrated Timer Measure Summary**

| Parameter                                          | Instant Savings                                                           | Reference                                                                              |
|----------------------------------------------------|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Measure Description and Identification             |                                                                           |                                                                                        |
| Measure Description                                | Power bars with integrated timer rebated in store                         | -                                                                                      |
| Baseline                                           | Power bars without an integrated timer, controlling a variety of end uses |                                                                                        |
| General Parameters                                 |                                                                           |                                                                                        |
| Installation Rate                                  | 100%                                                                      | See details below under Installation Rates                                             |
| Effective Useful Life [years]                      | 4                                                                         | See Subsection 3.2                                                                     |
| Electrical Savings Parameters                      |                                                                           |                                                                                        |
| Unitary Energy Savings [kWh/year]                  | 47.9                                                                      | See details below under Electrical Unitary Energy Savings                              |

| Unitary Peak Demand Savings [W]                    | 0.00                                                                      | Calculated by multiplying the unitary savings value by the peak demand-to-energy ratio |
| Interactive Effects Factor for Energy Savings      | 0%                                                                        | See Subsection 2.5.1                                                                   |
| Interactive Effects Factor for Peak Demand Savings | 0%                                                                        | See Subsection 2.5.1                                                                   |

### Electrical Unitary Energy Savings

Table 122 below presents the parameters used in equation below to calculate the electrical unitary savings resulting from the installation of power bars with integrated timers. The methodology and parameters used were drawn from the 2011 OPA Prescriptive Measures and Assumptions List,<sup>185</sup> with a minor adjustment to the number of days used per year; notably, the total 12-month period was set at 365 days instead of 12 times 30 days (360 days).

$$\begin{aligned}
 \text{Energy Savings} \left[ \frac{\text{kWh}}{\text{year}} \right] &= \text{Average Standby Wattage [W]} \times \frac{\text{kW}}{1,000 \text{ W}} \times (\text{Old Operating Time} - \text{New Operating Time}) \left[ \frac{\text{hrs}}{\text{day}} \right] \\
 &\times \text{Number of Days}
 \end{aligned}$$

<sup>185</sup> Ontario Power Authority (OPA), 2011 Prescriptive Measures and Assumptions Version 1, March 2011.

**Table 122: Electrical Unitary Savings Value for Power Bars with Integrated Timers**

| Parameter                                    | Entertainment Centre | Computer System | Lighting              | Other      |
|----------------------------------------------|----------------------|-----------------|-----------------------|------------|
| Proportion                                   | 40.3%                | 15.7%           | 19.4%                 | 24.6%      |
| Average Standby Wattage                      | 38.1 W               | 28 W            | 21.6 W <sup>186</sup> | 28 W       |
| Old Operating Time                           | 9 hrs/day            | 14 hrs/day      | 6 hrs/day             | 11 hrs/day |
| New Operating Time – with Timer              | 5 hrs/day            | 8 hrs/day       | 3 hrs/day             | 4 hrs/day  |
| Number of Days                               | 365                  | 365             | 259                   | 262        |
| Calculated Unitary Energy Savings [kWh/year] | 55.6                 | 61.3            | 16.8                  | 51.4       |
| Weighted Unitary Energy Savings [kWh/year]   | 47.9                 |                 |                       |            |

## Installation Rates

The installation rate is assumed to be 100%.

### (3) Heavy-duty Outdoor Timers

#### Summary

Table 123 below presents a summary of the values used to calculate heavy-duty outdoor timer savings. The detailed methodology follows.

**Table 123: Heavy-duty Outdoor Timer Measure Summary**

| Parameter                                          | Instant Savings                            | Reference                                                                              |

## Electrical Unitary Energy Savings

For heavy-duty outdoor timers, the electrical unitary energy savings value of 122 kWh is based on the results of the OPA 2012 Consumer Program Evaluation.<sup>187</sup> The survey conducted for that evaluation states that heavy-duty outdoor timers sold through the OPA biannual coupon program are used for outdoor lighting, pool pumps, and car block heaters, all of which correspond to possible usages for heavy-duty outdoor timers sold through Instant Savings. Table 124 presents the annual unitary savings value for Instant Savings.

**Table 124: Electrical Unitary Savings Values of Heavy-duty Outdoor Timers**

| Parameter                         | Value | Source                   |
|-----------------------------------|-------|--------------------------|
| Unitary Energy Savings [kWh/year] | 122   | OPA, 2012 <sup>188</sup> |

## Installation Rates

The installation rate is assumed to be 100%.

### (4) ENERGY STAR Certified Pool Pumps

#### Summary

Table 125 presents a summary of the values used to calculate ENERGY STAR certified pool pump savings. The detailed methodology follows.

## Electrical Unitary Energy Savings

The electrical unitary energy savings values of ENERGY STAR certified pool pumps are calculated using the equations below.

$$\text{Energy Savings} \left[ \frac{kWh}{yr} \right] = \text{Base Consumption} - \text{Reduced Consumption}$$

$$\text{Base Consumption} \left[ \frac{kWh}{yr} \right] = \text{Average Power} [kW] \times \text{Old HOU} \left[ \frac{h}{day} \right] \times \text{Pool Season} \left[ \frac{days}{yr} \right]$$

$$\text{Reduced Consumption} \left[ \frac{kWh}{yr} \right] = \text{Average Power} [kW] \times \text{RSF} [-] \times \text{New HOU} \left[ \frac{h}{day} \right] \times \text{Pool Season} \left[ \frac{days}{yr} \right]$$

The unitary savings value of 530 kWh comes from the 2020 NEEP TRM<sup>189</sup> and the Pool Pump Demand Response Potential Report.<sup>190</sup> The value is based on the difference in consumption between an average pool pump operating 5.18 hours per day during a 100-day pool season and a two-speed pool pump with the same power consumption but operating at its lower speed (half speed) for twice the operation time, which is 10.4 hours in this case. The savings are generated through pump affinity laws, which dictate that pump power is proportional to the cube of pump speed. Therefore, if a pump is operating at half speed, its power demand is at one-eighth its usual amount, and since it is operating for twice the usual time, the same amount of water is moved.

Table 126 presents the annual unitary savings value for Instant Savings.

**Table 126: Unitary Savings Values of ENERGY STAR Certified Pool Pumps**

| Parameter                         | Value | Reference                                                       |
|-----------------------------------|-------|-----------------------------------------------------------------|
| Average Power [kW]                | 1.36  | Pool Pump Demand Response Potential Report, 2008 <sup>191</sup> |
| Old Operating Time [h/day]        | 5.18  | Pool Pump Demand Response Potential Report, 2008 <sup>192</sup> |
| Pool Season [days/year]           | 100   | 2020 NEEP TRM <sup>193</sup>                                    |
| New Operating Time [h/day]        | 10.4  | Assumption                                                      |
| Reduced Speed Factor (RSF) [-]    | 0.125 | Pump affinity law convention                                    |
| Unitary Energy Savings [kWh/year] | 530   | Calculation                                                     |

## Installation Rates

The installation rate is assumed to be 100%.

## 2.6 Demand Reduction

For one category of demand reduction measures, namely demand response measures, the peak demand savings are replaced by the available DR capacity that differs from peak demand savings because the available DR capacity considers the potential load reduction that was made available instead of the actual load reduction that coincided with the actual utility peak.

### 2.6.1 Interactive Effects

For demand reduction measures, interactive effects are assumed to be nil.

### 2.6.2 Peak Demand Savings Factors

For demand reduction measures, peak demand savings are not determined using a peak demand-to-energy ratio since they do not generate energy savings. For more details, refer to Subsections 1.1.1(1), (2), (3), and 1.1.1(4).

### 2.6.3 Demand Reduction Measures

#### (1) Three-element Water Heaters

##### Summary

Table 127 presents a summary of the values used to calculate three-element water heater (TEWH) savings. The detailed methodology follows.

**Table 127: Three-element Water Heater Measure Summary**

| Parameter                                          | Green Heat                                         | Reference                                           |

## Electrical Unitary Energy Savings

No energy savings are expected from this measure.

## Unitary Peak Demand Savings

The unitary peak demand savings for three-element water heaters (TEWHs) were drawn from a Hydro-Québec study<sup>194</sup> that established the peak demand savings of 200 W based on tests performed on TEWHs during the 2007/2008 heating season. The results of that study were used since it was the only study found on TEWHs, the methodology is sound, and peak periods observed in the study include the Nova Scotia peak period.

## Installation Rates

Installation rates for three-element water heaters are estimated at 100% due to their relatively high cost.

### (2) Domestic Water Heater Timers

#### Summary

Table 128 presents a summary of the values used to calculate domestic water heater timer (DWHT) savings. The detailed methodology follows.

**Table 128: Domestic Water Heater Timer Measure Summary**

| Parameter                                          | Green Heat                                          | Reference                                                 |

## Electrical Unitary Energy Savings

No energy savings are expected from this measure.

## Unitary Peak Demand Savings

Since no information could be found in the literature, the peak demand savings of DWHTs were based on Nova Scotia Power estimates in their 2019 Load Forecast Report.<sup>195</sup>

In that report, the average peak contribution is estimated at 0.57 kW per tank. Therefore, shutting down the hot water system results in 0.57 kW in peak demand savings. This value is based on internal research on metered hot water tanks for which no details are available, except that the average tank power is approximately 3 kW and the coincident system peak of water heaters indicates that approximately one in five water heaters is on.

To account for uncertainties around this value, the peak demand savings were rounded down to 500 W. This value was deemed acceptable and conservative since it is lower than the baseline peak demand in the Hydro-Québec study for three-element water heaters.

## Installation Rates

Installation rates for DWHTs are estimated at 100% since they are installed and programmed by certified installers. In addition, the programming is locked after installation, meaning that participants need to contact the installer or Nova Scotia Power to prevent their interruption, leaving little room for savings to end prematurely.

### (3) Electric Thermal Storage

#### Summary

Table 129 presents a summary of the values used to calculate electric thermal storage savings. The detailed methodology follows.

| Interactive Effects Factor for Peak Demand Savings | 0%                                                          | See Subsection 2.6.1                                      |

## Electrical Unitary Energy Savings

No energy savings are expected from this measure.

## Unitary Peak Demand Savings

For electric thermal storage, an eight-hour charging period is assumed based on the residential off-peak period in Nova Scotia Power's time of day rate. It is also assumed that the stored heat is provided equally throughout the remaining 16 hours of the day.

Therefore, the unitary peak demand unitary savings for electric thermal storage are calculated using the equation below where the maximum storage capacity is drawn from manufacturer specification sheets and is the lowest value between either the maximum system storage capacity or the maximum amount of energy the system can store in eight hours.

$$Peak\ Demand\ Savings_W = \text{Maximum Storage Capacity in 8h} / 16h$$

## Installation Rates

Installation rates for electric thermal storage systems are estimated at 100% due to their relatively high cost.

## (4) Domestic Water Heater Load Control

### Summary

Table 130 presents a summary of the values used to calculate domestic water heater load control savings. The detailed methodology follows.

**Table 130: Domestic Water Heater Load Control Measure Summary**

| Parameter                                            | Demand Response                                                         | Reference                                                     |

| Available DR Capacity [W]                            | 385 ± 3%                                                                | See details below under Unitary Peak Demand Savings           |
| Interactive Effects Factor for Energy Savings        | N/A                                                                     | See Subsection 2.6.1                                          |
| Interactive Effects Factor for Available DR Capacity | 0%                                                                      | See Subsection 2.6.1                                          |

### Electrical Unitary Energy Savings

No energy savings are expected from this measure.

### Available DR Capacity

The unitary available DR capacity for domestic water heater load controls is based on the metering data analysis results from the 2023 Residential Demand Response evaluation. During the 2021-2022 and 2022-2023 heating seasons, E1 collected data for all participating units and all events. Using the metering data, it was established that each unit reduced demand by an average of 385 W during the two first hours when events were called.

### In-service Rates

While all controllers remained installed, connectivity issues resulted in not all controllers generating savings when events were called, the impact of which was included through the in-service rates as listed in Table 131.

**Table 131: Domestic Water Heater Load Control Measure In-service Rates**

| Type    | In-service Rate | Margin of Error | Source                         |
|---------|-----------------|-----------------|--------------------------------|
| Shifted | 81%             | 4%              | Residential DR 2023 Evaluation |

## 2.7 Renewables

### 2.7.1 Interactive Effects

Interactive effects are assumed to be nil for solar photovoltaic (PV) projects since the equipment involved in such systems is typically installed outdoors.

### 2.7.2 Peak Demand Savings Factors

For solar PV projects, peak demand savings are nil since the solar PV energy production from those systems coinciding with the peak period is negligible.

### 2.7.3 Renewable Measures

#### (1) Solar Photovoltaic Systems

##### Summary

Table 132 presents a summary of the values used to calculate savings for solar photovoltaic (PV) projects. The detailed methodology follows.

**Table 132: Solar Photovoltaic System Measure Summary**

| Parameter                                          | HEA                                                                 | Reference                                         |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for solar PV under HEA come from the average savings of projects rebated by SolarHomes (government funded). The SolarHomes project savings were calculated using the variables defined and listed in the equations and tables below. For each solar PV project, modelled energy production should be obtained either with PV Watts should include 14% of miscellaneous losses as pre-defined in the modelling tool, as well as a snow loss factor.

$$\text{Energy Savings per Project [kWh]} = \text{Modelled Energy Production [kWh]} \times \text{Adj. Ratio}$$

**Table 133: Electrical Savings Values for SolarHomes**

| Parameter                         | Symbol     | Value                                              | Reference                                                         |
|-----------------------------------|------------|----------------------------------------------------|-------------------------------------------------------------------|
| Modelled Energy Production [kWh]  | -          | Varies per project                                 | Project documentation, using PV Watts                             |
| Snow Loss Factor [%]              | -          | For panel tilt angles $\geq 25^\circ$ : 1%         | Northern Alberta Institute of Technology <sup>196</sup>           |
|                                   |            | For panel tilt angles $< 25^\circ$ : 4%            |                                                                   |
| Adjustment Ratio                  | Adj. Ratio | Projects modelled with PV Watts: 1.009             | Calibration study done as part of SolarHomes 2022/2023 Evaluation |
| Unitary Energy Savings [kWh/year] | -          | Calculated based on data for each installed system | Calculation                                                       |

For HEA, savings are calculated by multiplying the system capacity in kW by a factor of 1,086 kWh/kW, which was obtained by averaging the calibrated savings (i.e. including the 1.009 adjustment factor) for all 2021/2022 and 2022/23 projects in SolarHomes.

## Installation Rates

The installation rate is assumed to be 100% given the verification of the measure that is done through HEA's E assessment and the fact that the calibration study for SolarHomes would have captured any discrepancies in installed systems.

### 3 Effective Useful Life

This section outlines the EUL values used to calculate lifetime energy savings. This section also presents EUL values for demand reduction measures; these values are not used to calculate lifetime energy savings since those measures do not save energy. For demand response measures, the EUL represents the number of years for which the demand reduction is expected to persist. The EUL values should be used when calculating cost-effectiveness ratios for measures, in order to account for lifetime benefits.

#### 3.1 LED Lamps and Fixtures

To establish lifetime energy savings for LED lamps and fixtures, the equipment life is determined using rated lifetimes identified in product specification sheets and annual HOU, as described in the equation below.

$$\text{Equipment Life [Years]} = \frac{\text{Rated Lifetime [Hours]}}{\text{Annual HOU [Hours]}}$$

Since regulatory changes will cause the baseline to increase over the lifetime of LEDs and thus decrease annual savings over the lifetime of the product, an equivalent EUL is necessary to determine lifetime savings. The equivalent EUL is multiplied by first-year savings to obtain lifetime energy savings. Since the equivalent EUL is based on upcoming regulatory changes, it must be updated annually to take into account the changing duration of each baseline. The detailed assumptions and calculations to obtain equivalent EUL values are presented in Appendix II.

Table 134 summarizes the equivalent EUL values for residential LED lamps and fixtures.

**Table 134: EUL Values for Residential LED Lamps and Fixtures**

| Measure               | Program Component | Average Rated Lifetime (hours) | Annual HOU (hours/year) | Equipment Life (years) | 2024 Equivalent EUL (years) |
|-----------------------|-------------------|--------------------------------|-------------------------|------------------------|-----------------------------|
| <b>LED A19 Lamps</b>  |                   |                                |                         |                        |                             |
| 9 W Replacing 25 W    | EPI               | 25,000                         | 949                     | 26                     | 1.0                         |
| 9 W Replacing 29 W    |                   |                                |                         |                        | 1.0                         |

## 3.2 Other Measures

The EUL values for non-LED lighting measures were established by conducting a literature review of the most recent sources, notably technical reference manuals (TRMs) and studies, used in other jurisdictions.

Table 135 summarizes the EUL values and their source for residential measures.

**Table 135: EUL Values and Sources for Non-LED Lighting Residential Measures**

| Measure Name                             |                       |    |                                                                                                                                                                                                                                                                                                                                                   |

| Update      |                                                                           | (7) LED Nightlights                                                                                                                                                                                                               | EUL corrected to 1.0 to align with all other general-use lamp baseline change in 2025 |
| New Measure |                                                                           | (9) Horticultural Lighting                                                                                                                                                                                                        | Added horticultural lighting to BER-IR and BER-AR offerings                           |
| Update      | (4) Air-source Heat Pumps Less Than 65,000 Btu/h (excluding air-to-water) | Updated the baseline default Seasonal energy efficiency ratio (SEER) value                                                                                                                                                        | 2025-03-19                                                                            |
| Update      | 5.4.1 Water Heating Interactive Effects                                   | Modification of HP COP to 1.8                                                                                                                                                                                                     | 2025-03-19                                                                            |
| Update      | 5.4.4(1) Low-flow Showerheads                                             | Updated electric water heating efficiency                                                                                                                                                                                         | 2025-03-19                                                                            |
| Update      | 5.4.4(2) Faucet Aerators                                                  | Updated electric water heating efficiency                                                                                                                                                                                         | 2025-03-19                                                                            |
| Update      | 5.4.4(3) Thermostatic Shower Valve                                        | Updated electric water heating efficiency                                                                                                                                                                                         | 2025-03-19                                                                            |
| Update      | 5.4.4(5) Hot Water Tank Wraps                                             | Updated electric water heating efficiency                                                                                                                                                                                         | 2025-03-19                                                                            |
| Update      | (7) Efficient Refrigeration Compressors (Scroll Refrigeration Compressor) | Discus compressors are no longer in other TRMs and were also not rebated in recent years. We removed the discus compressors and simplified the algorithm to match Iowa's algorithm                                                | 2025-03-19                                                                            |
| Update      | (9) Brushless DC Motors                                                   | Updated the algorithm including the load factor and rated motor outputs                                                                                                                                                           | 2025-03-19                                                                            |
| Update      | (7) Dairy Scroll Compressors                                              | The milk weight and base EER were updated, along with the change in milk temperature                                                                                                                                              | 2025-03-19                                                                            |

## 4 Commercial Measure Assessment Scope

Table 137 below lists the commercial measures and associated programs included in the 2024-2025 DSM MA.

The MA includes all necessary parameters and calculations to obtain gross energy and peak demand savings for all portfolio prescriptive measures, as well as SBES and BER semi-prescriptive measures. The SBES and BER Application Rebate semi-prescriptive measures are added to the MA for the first time in 2024. In addition, effective useful life values are included for all prescriptive, semi-prescriptive, and custom measures.

For reference, savings calculations for prescriptive measures use fixed assumptions for all participants. The savings are identical for all units installed and represent the average savings for all units. Conversely, savings calculations for custom measures use inputs that are specific to each unit installed and thus represent the actual savings for each unit. Semi-prescriptive measures use a mix of two previous approaches by using unit-specific inputs as well as certain non-specific inputs to determine savings.

**Table 137: Included Commercial Measures**

| Program Components                                                                                                                                                                 |                      |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|
| <b>Lighting</b>                                                                                                                                                                    |                      |
| LED Lamps                                                                                                                                                                          | SBES                 |
| LED Linear Fixtures                                                                                                                                                                | BER-IR, BER-AR, SBES |
| LED Linear Lamps                                                                                                                                                                   | BER-IR, BER-AR, SBES |
| LED Outdoor Fixtures                                                                                                                                                               | BER-IR, BER-AR, SBES |
| LED Directional and Architectural Fixtures                                                                                                                                         | BER-IR, BER-AR, SBES |
| Occupancy Sensors                                                                                                                                                                  | BER-IR, BER-AR, SBES |
| LED Nightlights                                                                                                                                                                    | SBES                 |
| LED Roadway Lighting                                                                                                                                                               | BER-AR               |
| Horticultural Lighting                                                                                                                                                             | BER-AR               |
| <b>Pumps</b>                                                                                                                                                                       |                      |
| Circulator Pumps                                                                                                                                                                   | BER-IR, BER-AR       |

| Steam Cookers                                       | BER-AR, SBES |
| Ovens                                               | BER-AR, SBES |
| Kitchen Exhaust Demand Controlled Ventilation (DCV) | BER-AR, SBES |
| <b>Commercial IT and Datacentres</b>                |              |
| Server Virtualization and Decommissioning           | BER-AR, SBES |
| Server-based Power Management Software              | BER-AR, SBES |
| Uninterruptible Power Supply (UPS)                  | BER-AR, SBES |
| <b>Commercial Laundry Equipment</b>                 |              |
| Commercial Washing Machines                         | BER-AR, SBES |
| Commercial Clothes Dryers - Heat Pumps              | BER-AR, SBES |

## 5 BNI Measure Gross Savings Parameters

The following sections outline all necessary parameters to calculate gross energy savings for BER Instant Rebates, SBES and Custom Retrofit semi-prescriptive measures.

### 5.1 Lighting

#### 5.1.1 Interactive Effects

The interactive effects methodology for commercial lighting was reviewed as part of the 2024 DSM Measure Assessment update. The updated interactive effect factors and methodology are presented in Appendix IV. These updates will be applied in 2025 to align with updates to the BER-AR adjustment ratios also planned for 2025. Therefore, the interactive effect factors applied in 2024 are unchanged from 2023 and are presented below.

For BER Application Rebates and SBES (except for the direct install offer), the interactive effect factors are based on the building type as well as the space heating and cooling type specific to each project, as per the following two tables.

**Table 138: BER-AR Interactive Effects (IE) Factors for Lighting**

| Building Type                   | IE Peak Demand<br>(if electrical heating) | IE Energy          |                    |                                |
|---------------------------------|-------------------------------------------|--------------------|--------------------|--------------------------------|
|                                 |                                           | Electrical Heating | Electrical Cooling | Electrical Heating and Cooling |
| Agriculture                     | 0.75                                      | 0.81               | 1.04               | 0.85                           |
| Banking / Financial             | 0.74                                      | 0.8                | 1.04               | 0.84                           |
| Education                       | 0.74                                      | 0.8                | 1.04               | 0.84                           |
| Entertainment / Public Assembly | 0.71                                      | 0.78               | 1.04               | 0.82                           |
| Healthcare                      | 0.72                                      | 0.83               | 1.04               | 0.87                           |
| Hospitality                     | 0.69                                      | 0.81               | 1.04               | 0.85                           |
| Manufacturing / Industrial      | 0.7                                       | 0.77               | 1.06               | 0.83                           |

For indoor lighting measures offered through BER Instant Rebates, the interactive effects factors for energy and peak demand savings used are based on the average values of indoor lighting products installed through BER Application Rebates (BER-AR) and SBES in 2022 since no customer-specific information is available for BER Instant Rebates. In SBES and BER-AR, a standardized approach based on a methodology published in the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) Journal<sup>206</sup> is used to calculate the interactive effects for lighting projects on a per building-type basis. Additionally, the interactive effects factors are multiplied by 57% to consider the limited interaction of recessed fixtures with heating and cooling systems;<sup>207</sup> this factor applies to lighting measure categories that include recessed fixtures, namely LED linear fixtures and LED linear lamps.

For indoor lighting measures offered through the SBES direct install offer, the interactive effects factors used for energy and peak demand savings are based on the average values of indoor lighting products installed through SBES in 2022.

For outdoor lighting measures, interactive effects are nil.

Table 140 summarizes the interactive effects factors established for each lighting measure.

| LED Lamps                                  |              | -17.9%                                        | -31.8%                                             |
| LED Nightlights                            |              | -17.9%                                        | -31.8%                                             |

### 5.1.2 Peak Demand Savings Factors

Lighting measures use peak coincidence factor (PCF) for calculating peak demand savings. For indoor lighting measures offered through Instant Rebates, the PCF is based on the weighted average PCF value of all indoor lighting products installed through BER-AR and SBES in 2022 since no customer-specific information is available for BER Instant Rebates. The average PCF is 60%.

For indoor lighting measures offered through SBES CDI Pilot, the PCF is based on the average PCF value of indoor lighting products installed through SBES in 2022. The average PCF is 54%.

For outdoor lighting measures, since lighting is typically turned on between 5 p.m. and 7 p.m. throughout December, January, and February, a PCF of 100% is applied.

### Unitary Peak Demand Savings Calculations

Peak demand savings are calculated by multiplying the unitary demand savings value by the peak coincidence factor as detailed in the equation below.

$$\text{Unitary Peak Demand Savings (W)} = \text{Unitary Demand Savings (W)} \times \text{Peak Coincidence Factor (\%)}$$

The unitary demand savings value corresponds to the unitary energy savings divided by the hours of use (HOU), as presented in the equation below.

$$\text{Unitary Demand Savings (W)} = \frac{\text{Unitary Energy Savings (kWh)} \times 1,000}{\text{HOU (h)}}$$

### 5.1.3 Adjustment Ratios

The adjustment ratios in Table 141 were established through the latest comprehensive impact evaluation for each program. They should be applied for all lighting measures in SBES and BER-AR, except for CDI measures and LED roadway lighting measures.

**Table 141: 2023 Lighting Gross Savings Adjustments Ratios**

| Program Component                                      | Source Evaluation Report | Energy Savings   |                 | Peak Demand Savings |                 |
|--------------------------------------------------------|--------------------------|------------------|-----------------|---------------------|-----------------|
|                                                        |                          | Adjustment Ratio | Margin of Error | Adjustment Ratio    | Margin of Error |
| SBES Lighting Measures                                 | 2023                     | 1.070            | 5.3%            | 0.917               | 8.9%            |
| BER-AR Lighting Measures (except LED Roadway Lighting) | 2021                     | 0.993            | 6.7%            | 0.841               | 7.5%            |
| SBES CDI Pilot – A-type LED Lamps                      | 2019                     | 0.960            | 5%              | 0.960               | 5%              |
| SBES CDI Pilot – Other Products                        | 2019                     | 1.000            | -               | 1.000               | -               |
| BER-AR LED Roadway Lighting                            | -                        | 1.00             | -               | 1.00                | -               |

## 5.1.4 Lighting Measures

### (1) LED Lamps

#### Summary

Table 142 presents a summary of the values used to calculate A-type, reflector, and decorative LED lamp savings. These measures are only offered through the Commercial Direct Install (CDI) Pilot and use unitary savings values rather than measure-specific calculations. The detailed methodology follows.

**Table 142: LED Lamp Measure Summary**

| Parameter                                          | SBES                                                                     | Reference                                                                              |
|----------------------------------------------------|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Measure Description and Identification             |                                                                          |                                                                                        |
| Measure Description                                | LED lamps installed with direct installation                             | -                                                                                      |
| Baseline                                           | Existing lighting being replaced                                         |                                                                                        |
| Measure Subcategory                                | A-type, reflector, and decorative LED lamps                              |                                                                                        |
| General Parameters                                 |                                                                          |                                                                                        |
| Installation Rate                                  | 100%                                                                     | See details below under Installation Rates                                             |
| Energy Savings Adjustment Ratio                    | 0.960                                                                    | See Subsection 5.1.3                                                                   |
| Peak Demand Savings Adjustment Ratio               | 0.960                                                                    |                                                                                        |
| Effective Useful Life [years]                      | Varies depending on replaced and installed wattages as well as lamp type | See Subsection 6.1                                                                     |
| Electrical Savings Parameters                      |                                                                          |                                                                                        |
| Unitary Energy Savings [kWh/year]                  | Vary depending on replaced and installed wattages. See Table 143 below   | See details below under Electrical Unitary Energy Savings                              |
| Peak Coincidence Factor                            | 54%                                                                      | See Subsection 5.1.2                                                                   |
| Unitary Peak Demand Savings [W]                    | Vary depending on replaced and installed wattages. See Table 143 below   | Calculated by multiplying the unitary savings value by the peak demand-to-energy ratio |
| Interactive Effects Factor for Energy Savings      | -17.9%                                                                   | See Subsection 5.1.1                                                                   |
| Interactive Effects Factor for Peak Demand Savings | -31.8%                                                                   |                                                                                        |

#### Electrical Unitary Energy Savings

The equation below is used to determine the unitary savings values of LED lamps for each pairing of old and new wattages. Table 143 below lists the parameters and corresponding values used in the equation and the resulting unitary savings values.

$$\text{Energy Savings} \left[ \frac{kWh}{yr} \right] = \frac{(\text{Old Wattage} - \text{New Wattage})[W] \times \text{Operating Hours} \left[ \frac{h}{yr} \right]}{1,000 \left[ \frac{W}{kW} \right]}$$

**Table 143: Electrical Unitary Savings Values for LED Lamps**

| Type of LED                        | Old Wattage (W) | New Wattage (W) | Displaced Wattage (W) | Operating Hours (hrs/year) | Unitary Savings Value (kWh/year) |
|------------------------------------|-----------------|-----------------|-----------------------|----------------------------|----------------------------------|
| 9 W Replacing 25 W                 | 25              | 9               | 16                    | 3,600                      | 57.6                             |
| 9 W Replacing 29 W                 | 29              | 9               | 20                    |                            | 72.0                             |
| 9 W Replacing 40 W                 | 40              | 9               | 31                    |                            | 112                              |
| 9 W Replacing 43 W                 | 43              | 9               | 34                    |                            | 122                              |

| 5 W Chandelier E12 Replacing 40 W  | 40              | 5               | 35                    |                            | 126                              |

Previous evaluations confirmed that installed LED lamps had a light output wattage equivalent to that of the replaced lamps for almost all replacements. In other cases, the savings calculations are still based on the difference in real wattage values. The equivalent incandescent and halogen wattage values were assumed to be the same as those for the residential sector.

Average hours of operation of 3,600 hours were used for SBES indoor lighting products. These hours of operation are based on the average values of indoor lighting products installed through SBES in 2019.

## Unitary Peak Demand Savings

Unitary peak demand savings are calculated as described in Subsection 5.1.2.

**Table 144: Electrical Unitary Peak Demand Savings Values for LED Lamps**

| Type of LED                        | Displaced Wattage (W) | Peak Coincidence Factor (%) | Unitary Peak Demand Savings Value (W) |
|------------------------------------|-----------------------|-----------------------------|---------------------------------------|
| 9 W Replacing 25 W                 | 16                    | 54%                         | 8.6                                   |
| 9 W Replacing 29 W                 | 20                    |                             | 10.8                                  |
| 9 W Replacing 40 W                 | 31                    |                             | 16.7                                  |
| 9 W Replacing 43 W                 | 34                    |                             | 18.4                                  |
| 9 W Replacing 60 W                 | 51                    |                             | 27.5                                  |
| 9 W Replacing 72 W                 | 63                    |                             | 34.0                                  |

## Installation Rate

For light-emitting diode (LED) lamps in SBES, an installation rate of 100% was assumed.

## (2) Linear LED Fixtures

### Summary

Table 145 presents a summary of the values used to calculate linear LED fixture savings, followed by the detailed methodology.

**Table 145: Linear LED Fixture Measure Summary**

| Parameter                                          |              | BER-IR                                                                                                   | BER-AR                                         |       | SBES                                    | Reference                                                                         |

## Electrical Unitary Energy Savings

Table 146 lists the parameters and corresponding values used in the equation below to calculate unitary energy savings for LED linear fixtures.

$$\begin{aligned} \text{Energy Savings [kWh/yr]} \\ &= ((\text{Baseline Wattage} \\ &\quad - \text{New Wattage})[\text{W}] \times \text{HOU}[\text{h/day}] \times 365[\text{day/yr}]) / 1,000[\text{W/kW}] \end{aligned}$$

**Table 146: Electrical Unitary Energy Savings Values for Linear LED Fixtures**

| Parameter                         | Symbol                  | Value for BER-IR                                                | Value for BER-AR and SBES | Reference                                                                                                                           |
|-----------------------------------|-------------------------|-----------------------------------------------------------------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Baseline Wattage [W]              | <i>Baseline Wattage</i> | Fixed baseline based on fixture type and lumen output           | Actual                    | See Table 147 below for BER-IR                                                                                                      |
| New Wattage [W]                   | <i>New Wattage</i>      | Based on wattage listed in tracking sheet for each rebated unit | Actual                    | Use information in TS                                                                                                               |
| Hours of Operation [hrs/day]      | <i>HOU</i>              | 4,209                                                           | Actual                    | BER-IR value based on average HOU for indoor lighting products installed through BER-AR and SBES in 2021-2023 (excluding high bays) |
| Unitary Energy Savings [kWh/year] | <i>Energy Savings</i>   | Calculation based on specification data for each rebated unit   |                           | Calculated                                                                                                                          |

The linear LED fixtures category contains four subcategories of products eligible under Instant Rebates. Table 147 presents the baseline wattage used to calculate the energy savings for each of these subcategories based on lumens output. These wattages correspond to T8 fluorescent luminaires.

**Table 147: Linear LED Fixture Baseline Wattages for BER-IR**

| Subcategory                           | Lumens Output (lm) | Baseline Wattage (W) |
|---------------------------------------|--------------------|----------------------|
| 1 x 4 Luminaires                      | 1,500 – 3,500      | 61.0                 |
|                                       | ≥ 3,500            | 83.3                 |
| 2 x 2 Luminaires & Retrofit Kits      | 1,500 – 4,500      | 61.0                 |
|                                       | ≥ 4,500            | 84.0                 |
| 2 x 4 Luminaires & Retrofit Kits      | 3,000 – 6,500      | 88.0                 |
|                                       | ≥ 6,500            | 129                  |
| Linear Ambient and Low-bay Luminaires | < 2,500            | 29.5                 |
|                                       | 2,500 – 5,000      | 58.0                 |
|                                       | 5,000 – 10,000     | 112                  |
|                                       | ≥ 10,000           | 200                  |

## In-service Rate

The in-service rate for linear LED fixtures is estimated at 100% since it is unlikely that participants would purchase fixtures for stocking purposes.

### (3) Linear LED Lamps

#### Summary

Table 148 presents a summary of the values used to calculate linear LED lamp savings. The detailed methodology follows.

**Table 148: Linear LED Lamp Measure Summary**

| Parameter                                          |              | BER-IR                                                        | BER-AR                                          | SBES  | Reference                                                                         |
|----------------------------------------------------|--------------|---------------------------------------------------------------|-------------------------------------------------|-------|-----------------------------------------------------------------------------------|
| Measure Description and Identification             |              |                                                               |                                                 |       |                                                                                   |

## Electrical Unitary Energy Savings

Table 149 lists the parameters and corresponding values used in the equation below to calculate unitary energy savings for LED linear lamps.

$$\text{Energy Savings} \left[ \frac{kWh}{yr} \right] = \frac{(\text{Baseline Wattage} [W] \times \text{Ballast Factor} \times \text{Baseline Quantity} - \text{New Wattage} [W] \times \text{New Quantity}) \times HOU \left[ \frac{h}{day} \right] \times 365 \left[ \frac{day}{yr} \right]}{1,000 \left[ \frac{W}{kW} \right]}$$

**Table 149: Electrical Unitary Energy Savings Values for Linear LED Lamps**

| Parameter                         | Symbol                   | Value for BER-IR                                              | Value for BER-AR and SBES | Reference                                                                               |
|-----------------------------------|--------------------------|---------------------------------------------------------------|---------------------------|-----------------------------------------------------------------------------------------|
| Baseline Wattage [W]              | <i>Baseline Wattage</i>  | Based on fixture type and lumen output                        | Actual                    | Based on specification data for each rebated unit. See Table 150 below                  |
| Ballast Factor                    | <i>Ballast Factor</i>    | 0.88                                                          | Actual or default 0.88    | Assumption for normal ballast factor                                                    |
| Baseline Quantity                 | <i>Baseline Quantity</i> | Actual                                                        | Actual                    | Based on quantity listed in tracking sheet for each rebated unit                        |
| New Wattage [W]                   | <i>New Wattage</i>       | Actual                                                        | Actual                    | Based on wattage listed in tracking sheet for each rebated unit                         |
| New Quantity                      | <i>New Quantity</i>      | Actual                                                        | Actual                    | Based on quantity listed in tracking sheet for each rebated unit                        |
| Hours of Operation [hrs/day]      | <i>HOU</i>               | 4,209                                                         | Actual                    | Average HOU for indoor lighting products installed through BER-AR and SBES in 2021-2023 |
| Unitary Energy Savings [kWh/year] | <i>Energy Savings</i>    | Calculation based on specification data for each rebated unit |                           | <b>Calculated</b>                                                                       |

The linear LED lamp category contains six subcategories of products eligible under Instant Rebates. Table 150 presents the baseline wattage used to calculate the energy savings based on the Duke Energy Fixture Wattage Table.<sup>208</sup> These wattages correspond to T8 fluorescent luminaires.

**Table 150: Linear LED Lamp Baseline Wattage for BER-IR**

| Subcategory                          | Baseline Wattage (W) |
|--------------------------------------|----------------------|
| 2-foot Replacement Lamps             | 17                   |
| 3-foot Replacement Lamps             | 25                   |
| 4-foot Replacement Lamps             | 32                   |
| 8-foot Replacement Lamps             | 59                   |
| U-bend Replacement Lamps             | 31                   |
| 4-foot High Output Replacement Lamps | 49                   |

<sup>208</sup> Duke Energy Progress. Fixture Wattage Table. <http://www.ahutton.com/LED/Progress%20wattages.pdf>, (last accessed November 21, 2018).

## In-service Rate

Based on a study conducted by DNV-GL for the Massachusetts Energy Efficiency Program Administrators,<sup>209</sup> an in-service rate (ISR) of 85% is applied to LED lamps as part of BER-IR, which corresponds to the proportion of in-service fluorescent and LED lighting technologies installed three years after their purchase through an instant rebates program.

## (4) Outdoor LED Fixtures

### Summary

Table 151 presents a summary of the values used to calculate outdoor LED fixture savings. The detailed methodology follows.

**Table 151: Outdoor LED Fixture Measure Summary**

| Parameter                                          | BER-IR                                                           | BER-AR                                           | SBES  | Reference                                                                         |
|----------------------------------------------------|------------------------------------------------------------------|--------------------------------------------------|-------|-----------------------------------------------------------------------------------|
| Measure Description and Identification             |                                                                  |                                                  |       |                                                                                   |
| Measure                                            | Outdoor LED fixtures, rebated in store                           | Outdoor LED fixtures, rebated after installation |       | See Table 153 and Table 154 for BER-IR baseline                                   |
| Baseline                                           | Mix of metal halide (MH) and high pressure sodium (HPS) fixtures | Existing lamps                                   |       |                                                                                   |
| General Parameters                                 |                                                                  |                                                  |       |                                                                                   |

## Electrical Unitary Energy Savings

Table 152 lists the parameters and corresponding values used in the equation below to calculate unitary energy savings for outdoor LED fixtures.

$$\text{Energy Savings} \left[ \frac{kWh}{yr} \right] = \frac{(\text{Baseline Wattage} - \text{New Wattage})[W] \times HOU \left[ \frac{h}{day} \right] \times 365 \left[ \frac{day}{yr} \right]}{1,000 \left[ \frac{W}{kW} \right]}$$

**Table 152: Electrical Unitary Energy Savings Values for Outdoor LED Fixtures**

| Parameter                         | Symbol                  | Value for BER-IR                                              | Value for BER-AR and SBES | Reference                                                                                                                                                              |
|-----------------------------------|-------------------------|---------------------------------------------------------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Baseline Wattage [W]              | <i>Baseline Wattage</i> | Based on fixture type and lumen output                        | Actual                    | IR: See Table 153 for wall-mounted area luminaires and Table 154 for architectural and flood spot luminaires<br>AR: Based on specification data for each rebated unit. |
| New Wattage [W]                   | <i>New Wattage</i>      | Actual                                                        | Actual                    | Based on wattage listed in tracking sheet for each rebated unit                                                                                                        |
| Hours of Operation [hrs/day]      | <i>HOU</i>              | 4,317                                                         | Actual                    | Average HOU for outdoor lighting products installed through BER-AR and SBES in 2021-2023                                                                               |
| Unitary Energy Savings [kWh/year] | <i>Energy Savings</i>   | Calculation based on specification data for each rebated unit | Calculated                |                                                                                                                                                                        |

The outdoor LED fixture category contains outdoor wall-mounted area luminaires as well as the architectural flood and spot luminaire subcategories.

Both subcategories are divided into groups by lumens output to assign the correct baseline wattages, and the baseline technology used for each subcategory differs. Weighted averages of 50% MH and 50% HPS fixture system wattages are used to determine the baseline wattage values for outdoor full-cut-off, semi-cut-off, and non-cut-off wall-mounted area luminaires, as presented in Table 153.

**Table 153: Wattages per Lumens Output for Outdoor Wall-mounted Area Luminaires for BER-IR**

| Lumens Range          | MH Baseline Fixture Wattage (W) | HPS Baseline Fixture Wattage (W) | Weighted Average Baseline Wattage (W) |
|-----------------------|---------------------------------|----------------------------------|---------------------------------------|
| ≥ 300 and < 2,000     | 43                              | 46                               | 44.5                                  |
| ≥ 2,000 and < 5,000   | 95                              | 95                               | 95.0                                  |
| ≥ 5,000 and < 15,000  | 295                             | 250                              | 272.5                                 |
| ≥ 15,000 and < 25,000 | 458                             | 465                              | 461.5                                 |
| ≥ 25,000              | 850                             | 930                              | 890                                   |

The architectural flood and spot luminaire subcategory is divided into six ranges according to the baseline lamp technology. The typical lumens output of these fixtures is grouped into ranges to be able to select the appropriate efficient LED fixture depending on the required light output. A summary of the savings calculation parameters is provided in Table 154 below. The baseline technologies were derived from the Duke Energy Fixture Wattage Table.<sup>210</sup>

**Table 154: Wattages per Lumens Output for Architectural Flood and Spot Luminaires for BER-IR**

| Lumens Range of Efficient Luminaires | Baseline Fixture | Baseline Wattage (W) |
|--------------------------------------|------------------|----------------------|
| ≥ 250 and < 1,000                    | Halogen          | 37                   |
| ≥ 1,000 and < 5,000                  | MH (70 W)        | 95                   |
| ≥ 5,000 and < 15,000                 | MH (250 W)       | 295                  |
| ≥ 15,000 and < 30,000                | MH (250 W x 2)   | 590                  |
| ≥ 30,000 and < 50,000                | MH (1,000 W)     | 1,080                |
| ≥ 50,000                             | MH (1,500 W)     | 1,610                |

## In-service Rate

The in-service rate for outdoor LED fixtures is estimated at 100% since it is unlikely that participants would purchase fixtures for stocking purposes.

### Electrical Unitary Energy Savings

Table 156 lists the parameters and corresponding values used in the equation below to calculate unitary energy savings for directional and architectural LED fixtures.

$$Energy\ Savings\ \left[\frac{kWh}{yr}\right] = \frac{(Baseline\ Wattage - New\ Wattage)[W] \times HOU\ \left[\frac{h}{day}\right] \times 365\ \left[\frac{day}{yr}\right]}{1,000\ \left[\frac{W}{kW}\right]}$$

**Table 156: Electrical Unitary Energy Savings Values for Directional and Architectural LED Fixtures**

| Parameter                         | Symbol                  | Value for BER-IR                                              | Value for BER-AR and SBES | Reference                                                                                        |
|-----------------------------------|-------------------------|---------------------------------------------------------------|---------------------------|--------------------------------------------------------------------------------------------------|
| Baseline Wattage [W]              | <i>Baseline Wattage</i> | Based on fixture type and lumen output                        | Actual                    | <u>IR</u> : See Table 157 below<br><u>AR</u> : Based on specification data for each rebated unit |
| New Wattage [W]                   | <i>New Wattage</i>      | Actual                                                        | Actual                    | Use information in TS                                                                            |
| Hours of Operation [hrs/day]      | <i>HOU</i>              | 4,209                                                         | Actual                    | Average HOU for indoor lighting products installed through BER-AR and SBES in 2021-2023          |
| Unitary Energy Savings [kWh/year] | <i>Energy Savings</i>   | Calculation based on specification data for each rebated unit |                           | Calculated                                                                                       |

The directional and architectural LED fixture category contains track or mono-point directional luminaires. The baseline technology is halogen lamps generating 17 lumens/W. Table 157 presents the baseline wattage used to calculate the energy savings based on lumens output.

**Table 157: Directional and Architectural LED Fixture Baseline Wattages for BER-IR**

| Category                                   | Lumens     | Baseline Wattage (W) |
|--------------------------------------------|------------|----------------------|
| Track or Mono-point Directional Luminaires | ≥ 250      | 60.4                 |
| Wall-wash Luminaires                       | 517 - 1199 | 50.0                 |
|                                            | ≥ 1,200    | 100                  |

## In-service Rate

The in-service rate for directional and architectural LED fixtures is estimated at 100% since it is unlikely that participants would purchase fixtures for stocking purposes.

## (6) Occupancy/Motion Sensors

### Summary

Table 158 presents a summary of the values used to calculate occupancy/motion sensor savings. The detailed methodology follows.

**Table 158: Occupancy/Motion Sensor Measure Summary**

| Parameter                                          | BER-IR                                     |          | BER-AR                                                        | SBES  | Reference                                                                         |

### Electrical Unitary Energy Savings

Table 159 lists the parameters and corresponding values used in the equation below for occupancy and motion sensors and the resulting unitary values.

$$Energy\ Savings\ \left[\frac{kWh}{yr}\right] = Connected\ Wattage\ (W) \times Savings\ Factor\ (\%) \times OTF \times HOU/1,000$$

**Table 159: Electrical Unitary Energy Savings Values for Occupancy/Motion Sensors**

| Parameter                         | Type of Occupancy Sensor       | Value for BER-IR | Value for BER-AR and SBES                                     | Reference                                                                                                  |
|-----------------------------------|--------------------------------|------------------|---------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|

| Savings Factor (%)                | Ceiling or Wall Remote-Mounted | 24%              | See table below                                               |                                                                                                            |
|                                   | Fixture Mounted                |                  |                                                               |                                                                                                            |
|                                   | Wall Switch                    |                  |                                                               |                                                                                                            |
|                                   | Exterior                       | 41%              |                                                               |                                                                                                            |
| Operational Testing Factor (OTF)  | -                              | 1                |                                                               |                                                                                                            |
| Hours of Operation (HOU) [hrs/yr] | -                              | 3,799            | Actual                                                        | 2023 Efficiency Vermont TRM                                                                                |
| Unitary Energy Savings [kWh/year] | Interior                       | 100              | Calculation based on specification data for each rebated unit | Calculated                                                                                                 |
|                                   | Exterior                       | 134              |                                                               |                                                                                                            |

The connected wattage for occupancy/motion sensors is mostly based on the average connected wattage for units installed through BER-AR and SBES from January 2021 to July 2023. The only exception is for exterior motion sensors since only three were installed under these programs during that period. The connected wattage for exterior motion sensors is based on the value presented in the 2023 Efficiency Vermont TRM. The energy savings factors and the HOU are also based on the metering study referenced in the 2023 Efficiency Vermont TRM and are listed below.

**Table 160: Savings Factor per Control Type**

| Control Type               | Savings Factor % |
|----------------------------|------------------|
| Wall Occupancy Sensors     | 24%              |
| Fixture Mounted Occupancy  | 24%              |
| Remote Mounted Occupancy   | 24%              |
| Refrigerator Case Controls | 40%              |
| Freezer Case Controls      | 40%              |
| Exterior Occupancy         | 41%              |
| Fixture Mounted Daylight   | 28%              |
| Remote Mounted Daylight    | 28%              |

## In-service Rate

The in-service rate for occupancy/motion sensors is assumed to be 100%.

<sup>211</sup> Efficiency Vermont, *Technical Reference Manual (TRM): Program Year 2023*, 2023.

## (7) LED Nightlights

### Summary

Table 161 presents a summary of the values used to calculate savings for LED nightlights. The detailed methodology follows.

**Table 161: LED Nightlight Measure Summary**

| Parameter                                          | SBES                                                           | Reference                                                                         |
|----------------------------------------------------|----------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Measure Description and Identification             |                                                                |                                                                                   |
| Measure                                            | LED nightlights through direct installation                    | N/A                                                                               |
| Baseline                                           | Existing nightlight being replaced, which must be incandescent |                                                                                   |
| General Parameters                                 |                                                                |                                                                                   |

| Unitary Energy Savings [kWh/year]                  | 29.3                                                           | See details below under Electrical Unitary Energy Savings                         |
| Peak Coincidence Factor                            | 59%                                                            | See Subsection 5.1.2                                                              |
| Unitary Peak Demand Savings [W]                    | 3.95                                                           | Calculated by multiplying the demand savings value by the peak coincidence factor |
| Interactive Effects Factor for Energy Savings      | -17.9%                                                         | See Subsection 5.1.1                                                              |
| Interactive Effects Factor for Peak Demand Savings | -31.8%                                                         |                                                                                   |

### Electrical Unitary Energy Savings

Table 162 lists the parameters and corresponding values used in the equation below for LED nightlights and the resulting unitary values. The values for displaced wattages and hours of operation are consistent with the values used by other jurisdictions such as the State of Pennsylvania.<sup>212</sup>

$$Energy\ Savings\ \left[\frac{kWh}{yr}\right] = \frac{(Old\ Wattage - New\ Wattage)[W] \times HOU\ \left[\frac{h}{day}\right] \times 365\ \left[\frac{day}{yr}\right]}{1,000\ \left[\frac{W}{kW}\right]}$$

<sup>212</sup> Pennsylvania Public Utility Commission, *Technical Reference Manual – State of Pennsylvania*, August 2019, p. 7.

**Table 162: Electrical Unitary Energy Savings Values for LED Nightlights**

| Parameter                         | Value | Reference                                                                   |
|-----------------------------------|-------|-----------------------------------------------------------------------------|
| Old Wattage [W]                   | 7.0   | Assumption based on the typical wattage value of an incandescent nightlight |
| New Wattage [W]                   | 0.3   | Wattage value of the LED nightlight installed through SBES (E1)             |
| Average Displaced Wattage [W]     | 6.7   | Calculation                                                                 |
| Hours of Operation [hrs/day]      | 12    | Assumption based on the average length of night                             |
| Unitary Energy Savings [kWh/year] | 29.3  | Calculation                                                                 |

## Unitary Peak Demand Savings

Unitary peak demand savings are calculated as described in Subsection 5.1.2.

## Installation Rates

An in-service rate of 100% was assumed since SBES LED nightlights are currently only offered through a direct install service; such services typically have installation rates close to 100% for lighting products.

## (8) LED Roadway Lighting

### Summary

Table 163 presents a summary of the values used to calculate savings for LED roadway lighting. The detailed methodology follows.

**Table 163: LED Roadway Lighting Measure Summary**

| Parameter                                          | BER-AR                                                                                                                                                      | Reference                                                                         |

| Unitary Peak Demand Savings [W]                    | Calculation based on specification data for each rebated unit                                                                                               | Calculated by multiplying the demand savings value by the peak coincidence factor |
| Interactive Effects Factor for Energy Savings      | 0%                                                                                                                                                          | See Subsection 5.1.1                                                              |
| Interactive Effects Factor for Peak Demand Savings | 0%                                                                                                                                                          |                                                                                   |

### Electrical Unitary Energy Savings

Table 164 lists the parameters and corresponding values used in the equation below for LED roadway lighting and the resulting unitary values.

$$Energy\ Savings\ \left[\frac{kWh}{yr}\right] = \frac{(Old\ Wattage - New\ Wattage)[W] \times HOU\ \left[\frac{h}{yr}\right]}{1,000\ \left[\frac{W}{kW}\right]}$$

**Table 164: Electrical Unitary Energy Savings Values for LED Roadway Lighting**

| Parameter                         | Value                 | Reference                                                     |
|-----------------------------------|-----------------------|---------------------------------------------------------------|
| Old Wattage [W]                   | Actual                | Use information in TS                                         |
| New Wattage [W]                   | Actual                | Use information in TS                                         |
| Hours of Operation [hrs/year]     | Actual or 4662        | Calculated based on sunset and sunrise times for Nova Scotia  |
| Unitary Energy Savings [kWh/year] | <i>Energy Savings</i> | Calculation based on specification data for each rebated unit |

## Unitary Peak Demand Savings

Unitary peak demand savings are calculated as described in Subsection 5.1.2.

## Installation Rates

An installation rate of 100% was assumed in the absence of measured data, since roadway lighting

## (9) Horticultural Lighting

### Summary

Table 165 presents a summary of the values used to calculate savings for horticultural lighting. The detailed methodology follows.

**Table 165: Horticultural Lighting Measure Summary**

| Parameter                                          | BER-AR                                                        |                           | Reference                                                 |
|----------------------------------------------------|---------------------------------------------------------------|---------------------------|-----------------------------------------------------------|
|                                                    | Retrofit                                                      | New Construction          |                                                           |
| Measure Description and Identification             |                                                               |                           |                                                           |
| Measure Description                                | Horticultural lighting rebated after installation             |                           | -                                                         |
| Baseline                                           | Existing lighting                                             | Metal halide HID fixtures |                                                           |
| General Parameters                                 |                                                               |                           |                                                           |

## **5.2 Pumps**

### **5.2.1 Interactive Effects**

For pumps, interactive effects are assumed to be nil because pumps are typically installed in non-conditioned spaces.

### **5.2.2 Peak Demand Savings Factors**

For pumps, the methodology used to determine peak demand savings is detailed in the measure-specific sections below.

### **5.2.3 Adjustment Ratios**

For pump measures, no adjustment ratios were calculated.

## 5.2.4 Pump Measures

### (1) Circulator Pumps

#### Summary

Table 168 presents a summary of the values used to calculate circulator pump savings. The detailed methodology follows.

**Table 168: Circulator Pump Measure Summary**

| Parameter                                          | BER-IR, BER-AR                                                                          |                                     |                                       | Reference                                                 |

#### Electrical Energy Unitary Savings

The electrical energy unitary savings for circulator pumps are calculated using the equation below and savings data from Vermont adapted to Nova Scotia using each jurisdiction's average operating hours. Although the max input power tiers defined in the Vermont TRM and those defined by E1 differ, the difference is considered minimal, thus E1's tiers have been used in the savings assumptions for this measure. Table 169 below lists the parameters used for the calculation of electrical energy unitary savings.

$$\text{Unitary Energy Savings} \left[ \frac{kWh}{yr} \right] = UES_{VT} \left[ \frac{kWh}{yr} \right] \times \frac{HOU_{NS} \left[ \frac{hours}{yr} \right]}{HOU_{VT} \left[ \frac{hours}{yr} \right]}$$

**Table 169: Electrical Unitary Energy Savings Values for Circulator Pumps**

## Unitary Peak Demand Savings

The unitary demand savings value corresponds to the unitary energy savings divided by the HOU, as presented in the equation below.

### **Unitary Demand Savings [W]**

$$= (\text{Unitary Energy Savings [kWh]}) / (\text{HOU [h]} \times 1,000) \times \text{Peak Coincidence Factor [(\%)]}$$

Since circulator pumps are typically used as part of residential and commercial hydronic heating system applications, it is assumed that they operate continuously during the coldest days of winter. Thus, a PCF of 100% is applied to this measure category.

The unitary peak demand unitary savings for circulator pumps are calculated using the parameters listed in Table 170.

**Table 170: Unitary Peak Demand Savings Values for Circulator Pumps**

| Parameters                      | BER-IR                  |                                     |                                       | Reference                       |
|---------------------------------|-------------------------|-------------------------------------|---------------------------------------|---------------------------------|
|                                 | Max Input Power < 150 W | Max Input Power ≥ 150 W and < 500 W | Max Input Power ≥ 500 W and < 2,500 W |                                 |
| Average Demand Savings [kW]     | 0.0675                  | 0.0953                              | 0.1270                                | 2018 Vermont TRM <sup>217</sup> |

### Electrical Unitary Energy Savings

The electrical unitary energy savings for booster pumps are calculated using the variables defined and listed in the equation and Table 172 below.

$$Energy\ Savings_{kWh} = 891.20 \times HP_{ee} + 3,523.08 \times \Delta HP_{sys}$$

**Table 172: Electrical Unitary Energy Savings Values for Booster Pumps**

| Parameter                                                                                      | Symbol                  | BER-AR                             | Reference                      |
|------------------------------------------------------------------------------------------------|-------------------------|------------------------------------|--------------------------------|
| Rated Horsepower of the New Booster Pump or Pumping System [HP]                                | $HP_{ee}$               | Specification data for each system | Tracking sheet                 |
| Reduction in the Total Rated Horsepower of the System [HP]                                     | $\Delta HP_{sys}$       | Specification data for each system | Tracking sheet                 |
| Annual Unitary Energy Savings per Rated Horsepower from the Use of a VFD Booster Pump [kWh/HP] | -                       | 891.20                             | 2020 Hawaii TRM <sup>218</sup> |
| Annual Unitary Energy Savings per Rated Horsepower Reduced [kWh/HP]                            | -                       | 3,523.08                           |                                |
| Unitary Energy Savings [kWh/year]                                                              | $Energy\ Savings_{kWh}$ | 657                                | Calculation                    |

## Unitary Peak Demand Savings

The unitary peak demand savings for booster pumps are calculated using the variables defined and listed in the equation and Table 173 below, as well as variables from Table 172 above.

$$Peak\ Demand\ Savings_W = (172 \times HP_{ee} + 671 \times \Delta HP_{sys}) \times PCF$$

**Table 173: Unitary Peak Demand Savings Values for Booster Pumps**

| Parameter                                                                                    | Symbol                    | BER-AR | Reference                                                                                    |
|----------------------------------------------------------------------------------------------|---------------------------|--------|----------------------------------------------------------------------------------------------|
| Annual Unitary Demand Savings per Rated Horsepower from the Use of a VFD Booster Pump [W/HP] | -                         | 172    | 2020 Hawaii TRM <sup>219</sup>                                                               |
| Annual Unitary Demand Savings per Rated Horsepower Reduced [W/HP]                            | -                         | 671    |                                                                                              |
| Peak Coincidence Factor                                                                      | $PCF$                     | 0.7    | Average value calculated using project data from eight Custom Retrofit booster pump projects |
| Unitary Peak Demand Savings [W]                                                              | $Peak\ Demand\ Savings_W$ | 88.8   | Calculation                                                                                  |

## Installation Rates

Installation rates for booster pumps are estimated at 100%.

## 5.3 HVAC

### 5.3.1 Interactive Effects

For HVAC measures, interactive effects are assumed to be nil.

### 5.3.2 Peak Demand Savings Factors

For all HVAC measures, the methodology used to determine peak demand savings is detailed in the measure-specific sections below.

### 5.3.3 Adjustment Ratios

The adjustment ratios in Table 174 were established through the latest comprehensive impact evaluation for each program. They should be applied for all HVAC measures in SBES and BER-AR.

**Table 174: 2023 HVAC Gross Savings Adjustment Ratios**

| Program Component | Source Evaluation Report | Energy Savings   |                 | Peak Demand Savings |                 |
|-------------------|--------------------------|------------------|-----------------|---------------------|-----------------|
|                   |                          | Adjustment Ratio | Margin of Error | Adjustment Ratio    | Margin of Error |
| SBES              | 2023                     | 0.980            | 4.4%            | 1.009               | 8.6%            |
| BER-AR            | 2022                     | 1.002            | 0.3%            | 1.000               | 2.1%            |

## 5.3.4 HVAC Measures

### (1) Electric Thermal Storage

#### Summary

Table 175 presents a summary of the values used to calculate electric thermal storage savings. The detailed methodology follows.

**Table 175: Electric Thermal Storage Measure Summary**

| Parameter                                          | BER-AR                                                                                                | SBES  | Reference                                                 |

#### Electrical Unitary Energy Savings

No energy savings are expected from this measure.

## Unitary Peak Demand Savings

For electric thermal storage, an eight-hour charging period is assumed based on the residential off-peak period in Nova Scotia Power's time of day rate. It is also assumed that the stored heat will be provided equally throughout the remaining 16 hours of the day.

Therefore, the unitary peak demand unitary savings for electric thermal storage are calculated using the equation below where the maximum storage capacity is drawn from manufacturer specification sheets and is either the maximum system storage capacity or the maximum amount of energy the system can store in eight hours.

$$\text{Peak Demand Savings}_W = \text{Maximum Storage Capacity in 8h/16h}$$

## (2) Advanced Rooftop Unit Controls

### Summary

Table 176 presents a summary of the values used to calculate advanced rooftop unit (RTU) control savings. The detailed methodology follows.

**Table 176: Advanced RTU Control Measure Summary**

| Parameter                                          | BER-AR                                                                                                                                            | Reference                                                 |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for advanced RTU controls are calculated using the variables defined and listed in the equation below as well as in Table 177 and Table 178 further below.

$$\begin{aligned} \text{Energy Savings}_{kWh} &= \frac{1}{12,000} \times \left( \text{Capacity}_{cool} \times (AC \times CESF_{DCV} + VFD \times FESF_{VFD}) \right) \\ &+ \text{ElecHeat} \times \frac{\text{Capacity}_{heat} \times HESF_{DCV}}{COP_{heat}} \end{aligned}$$

**Table 177: Electrical Unitary Energy Savings Values for Advanced RTU Controls**

| Other/Miscellaneous <sup>229</sup>       | 692                                                                   | 4                                                                 | 1,241                                                             |

<sup>224</sup> Supply fan energy savings factors were calculated based on the difference between the normalized energy savings per cooling capacity values for the Chicago DCV and VFD w/3-speed fan control and DCV scenarios of the Advanced Rooftop Controls measure in the 2021 Illinois TRM.

<sup>225</sup> Cooling energy savings factors for DCV were calculated based on the normalized energy savings per cooling capacity values for the Chicago DCV scenario of the Advanced Rooftop Controls measure in the 2021 Illinois TRM as well as the cooling degree days from Chicago (1,865°C·day, 2021 Illinois TRM) and Halifax (325°C·day, Government of Canada).

<sup>226</sup> Heating energy savings factors for DCV were calculated based on the normalized energy savings per heating capacity values for the Chicago DCV scenario of the Advanced Rooftop Controls measure in the 2021 Illinois TRM as well as the heating degree days from Chicago (2,238°C·day, 2021 Illinois TRM) and Halifax (3,378°C·day, Government of Canada). Heating energy savings factors per capacity were multiplied by the COP assumption of 2.3 (2021 Illinois TRM) to obtain heating energy savings factors per capacity and COP.

<sup>227</sup> For primary and secondary education facilities, supply fan energy savings factors were assumed to be the same as for community college/university facilities, and cooling and heating energy savings factors were calculated based on the ratio of their full load heating and cooling hours and those of community college/university facilities (from the 2016 EPR Evaluation Report). Similarly, the savings factors for hospitals were based on the values for clinics, those for multi-family facilities were based on the values for lodging facilities, and those for mid-rise and high-rise offices were based on the values for low-rise offices.

<sup>228</sup> Energy savings factors for assisted living facilities were used for clinics and lodging facilities as they were assumed to be similar.

<sup>229</sup> Energy savings factors for the Other/Miscellaneous category were estimated to be the average values of all other categories.

## Unitary Peak Demand Savings

The unitary peak demand savings for advanced RTU controls that include a supply fan VFD are calculated using the variables defined and listed in the equation as well as in Table 179 below. For the DCV portion of advanced RTU controls, no unitary peak demand savings that could be adapted to the Nova Scotia load shape were found in the literature. To claim DCV peak demand savings, metering or simulation data would have to be collected.

$$\text{Peak Demand Savings}_W = VFD \times HP \times 1,000 \times DSVG \times PCF$$

#### Electrical Unitary Energy Savings

The electrical unitary energy savings for smart thermostats for electric baseboards for commercial applications are assumed to be equal to the savings for a residential application because the heating power of controlled thermostats is expected to be similar. The residential savings were calculated according to the equation and methodology below.

$$Energy\ Savings_{kWh} = \frac{Heating\ Energy \times \%Savings \times FMT}{COP}$$

Since no studies specific to smart thermostats connected to electric baseboards, mini-split heat pump (MSHPs), or electric in-floor heating systems were identified, the percentage of the heating load saved by thermostats is based on available studies for smart thermostats compatible with central heating systems, which have essentially the same features. Table 181 presents two billing analyses conducted for Nest smart thermostats installed on central electrical heating systems (rather than natural gas or oil heating systems). Both analyses served to assess the savings for smart thermostats installed to replace both programmable and non-programmable thermostats, which is a reasonable baseline. In both studies, heating consumption savings of 12% were evaluated for central air-source heat pumps, which is the closest heating system to electric baseboards.

**Table 181: Billing Analysis Savings Results for Smart Thermostats for Electrical Heating Systems**

| Jurisdiction                                   | Measure          | Sample Size | Heating Consumption Savings |
|------------------------------------------------|------------------|-------------|-----------------------------|
| Oregon <sup>231</sup>                          | Nest thermostats | 185         | 12% (for ASHPs)             |
| Bonneville Power Administration <sup>232</sup> | Nest thermostats | 176         | 12% (for ASHPs)             |

The savings are divided by the average number of electric heating systems within a dwelling and assuming there is one heating system and one thermostat controlling the system in each room.

Table 182 below presents the variables used for the unitary savings calculation and the resulting value per thermostat.

## Unitary Peak Demand Savings

Smart thermostats are assumed to generate no peak demand savings.

<sup>233</sup> Based on the average modelled heating energy consumption of HEA participants before and after their home retrofit, including 100% electrically heated participants with no heat pumps and adjusted to take into account HOT2000 overestimation ratios from the 2018 billing analysis. The averages of each year were weighted according to the number of projects.

<sup>234</sup> Assuming 1 thermostat per room for electric baseboards and in-floor heating and 6.5 rooms on average based on Statistics Canada 2016 Census. For MSHP, Assuming 1 thermostat per indoor unit and 2 indoor units per home. Statistics Canada, Census Profile, 2016 Census, <https://www12.statcan.gc.ca/census-recensement/2016/dp-pd/prof/details/Page.cfm?Lang=E&Geo1=PR&Code1=12&Geo2=&Code2=&Data=Count&SearchType=Begin&SearchPR=01&B1=All> (last accessed December 3, 2019).

<sup>235</sup> Assuming a COP of 1 for electric resistance (including baseboard and in-floor), a COP of 1.8 for heat pumps and an average HSPF2 of 6.0 for Region V, which corresponds to the minimum for "Split system central heat pumps, other than those that are small-duct and high-velocity or space-constrained" as per the NRCan regulation available at <https://natural-resources.canada.ca/energy-efficiency/energy-efficiency-regulations/guide-canadas-energy-efficiency-regulations/split-system-central-air-conditioners-and-heat-pumps/6895>.

## (4) Air-source Heat Pumps Less Than 65,000 Btu/h (excluding air-to-water)

### Summary

Table 183 presents a summary of the values used to calculate the savings for air-source heat pumps (ASHPs) of less than 65,000 Btu/h (excluding air-to-water). The detailed methodology follows.

**Table 183: Air-source Heat Pumps Less Than 65,000 Btu/h, Measure Summary**

| Parameter                                          | BER-AR                                                                                                                                              | SBES  | AMH (prescriptive)   | AMH (comprehensive)                   | Reference                                                 |

<sup>236</sup> This adjustment ratio is only meant to be applied in the 2024 AMH evaluation due to the fact that residential equivalent full load hour values were not adjusted last year following the change from HSPF to HSPF2. Going forward, the new equivalent full load hour values will be used.

## Electrical Unitary Energy Savings

The electrical unitary energy savings for ASHPs of less than 65,000 Btu/h (excluding air-to-water) are calculated using the variables defined and listed in the equation<sup>237</sup> and Table 184 below.

$$\Delta kWh = \left( HC * \left[ \frac{1}{HSPF2_{base}} - \frac{1}{HSPF2_{ee}} \right] * FLH_h + CC * \left[ \frac{1}{SEER2_{base}} * AC - \frac{1}{SEER2_{ee}} \right] * FLH_c \right)$$

**Table 184: Electrical Unitary Energy Savings Values for Air-source Heat Pumps Less Than 65,000 Btu/h**

**Table 185: Full Load Heating and Cooling Hours for BER-AR and SBES**

| Facility Type                            | FLHh  | FLHc |
|------------------------------------------|-------|------|
| Convenience Store                        | 1,887 | 647  |
| Education - Community College/University | 1,972 | 682  |
| Education - Primary                      | 2,394 | 289  |
| Education - Secondary                    | 2,561 | 484  |
| Health/Medical - Clinic                  | 2,234 | 558  |
| Health/Medical - Hospital                | 2,508 | 663  |
| Lodging                                  | 2,361 | 401  |
| Manufacturing                            | 1,397 | 347  |
| Multi-Family                             | 2,280 | 228  |
| Office - Low Rise                        | 1,966 | 257  |
| Office - Mid Rise                        | 2,189 | 373  |
| Office - High Rise                       | 2,149 | 669  |
| Restaurant                               | 1,868 | 347  |
| Residential (AMH only)                   | 898   | 213  |
| Retail - Large Department Store          | 1,763 | 462  |
| Retail - Strip Mall                      | 1,701 | 307  |
| Warehouse                                | 1,872 | 164  |
| Other/Miscellaneous                      | 2,123 | 443  |

For AMH, most heat pumps are installed in dwelling where people live and used in a residential fashion. Therefore, it was decided to use a residential FLH value derived from the 2017 Green Heat billing analysis, unless people do not actually live in the dwellings, like when they only sleep there. For example, the residential FLH value should not be used for shelters and community centers.

## Unitary Peak Demand Savings

The unitary peak demand savings for ASHPs of less than 65,000 Btu/h (excluding air-to-water) are calculated using the variables defined and listed in the equation and Table 186 below, as well as variables from Table 184 above. The equation is from the Vermont 2023 TRM<sup>240</sup> with the performance taken at -15°C, which is the estimated temperature during the Nova Scotia peak demand period. If the heat pump is not operational at -15°C, there are no peak demand savings.

$$\Delta kW = \frac{HC_{min}}{HSPF_{base}} \times \left[ 1 - \frac{1}{COP_{ee\_min}} \right] \times PCF$$

<sup>240</sup> Efficiency Vermont, *Technical Reference Manual (TRM) Program Year 2023*, p.90.

## **(5) Air-source Heat Pumps Greater Than or Equal to 65,000 Btu/hr; Ground-source Heat Pumps; Water Source Heat Pumps; Air-to-water Heat Pumps; and Packaged Terminal Heat Pumps (PTHPs)**

### **Summary**

Table 187 presents a summary of the values used to calculate the savings for ASHPs greater than or equal to 65,000 Btu/h. The same methodology is used for ground-source heat pumps, water-source heat pumps, air-to-water heat pumps, and packaged terminal heat pumps. The detailed methodology follows.

**Table 187: Air-source Heat Pumps Greater Than 65,000 Btu/h, Measure Summary**

## Electrical Unitary Energy Savings

The electrical unitary energy savings for ASHPs greater than 65,000 Btu/h calculated using the variables defined and listed in the equation<sup>241</sup> and Table 188 below.

$$\Delta kWh = \left( HC * \left[ \frac{1}{HEF_{base}} - \frac{1}{HEF_{ee}} \right] * FLH_h + CC * \left[ \frac{1}{CEF_{base}} * AC - \frac{1}{CEF_{ee}} \right] * FLH_c \right)$$

<sup>241</sup> Efficiency Vermont, *Technical Reference Manual (TRM) Program Year 2023*, p.90.

## Unitary Peak Demand Savings

The unitary peak demand savings for ASHP great than 65,000 Btu/h are calculated using the variables defined and listed in the equation and Table 190 below, as well as variables from Table 188 above. The equation is from the Vermont 2023 TRM<sup>243</sup> with the performance taken at -15°C, which is the estimated temperature during Nova Scotia Peak Demand. If the heat pump is not operational at -15°C, there are no peak demand savings.

$$\Delta kW = HC_{min} * \left[ 1 - \frac{1}{HEF_{ee,min}} \right] \times PCF$$

<sup>243</sup> Efficiency Vermont, *Technical Reference Manual (TRM) Program Year 2023*, p.90.

## Electrical Unitary Energy Savings

The electrical unitary energy savings for dual enthalpy economizer controls are calculated using the variables defined and listed in the equation<sup>244</sup> and Table 192 below.

$$\Delta kWh = SF \times Tonnes \times \frac{OTF}{EER} \times Quantity$$

**Table 192: Electrical Unitary Savings Values for Dual Enthalpy Economizer Controls**

| Parameter                             | Symbol       | BER-AR, SBES                                                  | Reference                                                                                                                                                                                                                                                                        |
|---------------------------------------|--------------|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Unitary Peak Demand Savings

The unitary peak demand savings for dual enthalpy economizer controls are assumed to be nil, because air conditioning loads are likely to be nil under peak conditions at -15°C.

## Installation Rates

Installation rates for dual enthalpy economizer controls are estimated at 100%.

## (7) HVAC Hotel Occupancy Sensors

### Summary

Table 193 presents a summary of the values used to calculate HVAC hotel occupancy sensor savings. The detailed methodology follows.

<sup>244</sup> Efficiency Vermont, *Technical Reference User Manual Measure Savings Algorithms and Cost Assumptions*, March 2015.

<sup>245</sup> Efficiency Vermont, *Technical reference User Manual*, March 16, 2015.

**Table 193: HVAC Hotel Occupancy Sensor Measure Summary**

| Parameter                                          | BER-AR                                                                                                                                                        | SBES  | Reference                                                                     |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for HVAC hotel occupancy sensors are defined in Table 194 below.

**Table 194: Electrical Unitary Energy Savings Values for HVAC Hotel Occupancy Sensors**

| Parameter                         | Symbol | BER-AR, SBES | Reference                              |
|-----------------------------------|--------|--------------|----------------------------------------|
| Unitary Energy Savings [kWh/year] | -      | 438          | Massachusetts TRM, 2012 <sup>246</sup> |

## Unitary Peak Demand Savings

The unitary peak demand savings for HVAC hotel occupancy sensors are provided in Table 195 below, as well as variables from Table 194 above.

<sup>246</sup> Massachusetts, *Technical Reference User Manual (TRM) for Estimating Savings from Energy Efficiency Measures*, October 2012.

**Table 195: Unitary Peak Demand Savings Values for HVAC Hotel Occupancy Sensors**

| Parameter                        | Symbol | BER-AR, SBES | Reference               |
|----------------------------------|--------|--------------|-------------------------|
| Unitary Peak Demand Savings [kW] | -      | 0.09         | Massachusetts TRM, 2012 |

## Installation Rates

Installation rates for HVAC hotel occupancy sensor are estimated at 100%.

## 5.4 Water Heating

### 5.4.1 Interactive Effects

Interactive effects are assumed to be nil for all water heating measures except for hot water insulation measures.

### Hot Water Insulation Measures

For hot water insulation measures, namely pipe insulation and hot water tank wraps, the interactive effects factors are based on engineering calculations to account for the duration of the heating and cooling seasons, cooling and heating system efficiency, and percentage of heat generated inside the heated portion of the building envelope.

For SBES, since no information is currently available on the proportion of water heating systems that are located inside the heated portion of the building for small businesses, the Evaluator assumed that it is similar to those of single-family homes. As presented in the Residential Subsection 2.2.1, based on site visit results from the 2015 evaluation<sup>247</sup> and accounting for the proportion of DHW insulation measures installed in conditioned spaces, the average number of months during which heating interactive effects occur in a single-family home is 3.8 months. It is assumed that the impact of DHW on cooling loads is negligible since most measures are installed in a location that might be heated but not likely air-conditioned. Similar to lighting measures, it is assumed that 10% of the heat released by the pipes and DHW is lost through exterior walls and ceilings and does not contribute to the interactive effects, meaning 90% of heating contributes to interactive effects.

For buildings with heat pump heating, since the interactive effects factors are based on a heating system efficiency of 100%, some adjustments are necessary for buildings that use a heat pump as a primary heating system because the efficiency of such systems is superior to 100%. To do so, the interactive effects factor for heating (-28.5%) is divided by 1.8, the COP of a standard mini-split heat pump based on an HSPF2 Region V of 6.0, which is the value for a standard split heat pump as defined by the Federal Energy Efficiency Regulations.<sup>248</sup>

### Peak Demand

As for the impact on peak demand savings, it is assumed that all hot water tanks in a conditioned or semi-conditioned space create interactive effects. Therefore, similar to lighting products, the interactive effects factor for peak demand savings in electrically heated buildings is -90%.

<sup>247</sup> Econoler, *Residential Direct Install 2015 Evaluation*, March 3, 2016.

<sup>248</sup> Minister of Justice, Canada, *Energy Efficiency Regulations, 2016*, <http://laws-lois.justice.gc.ca/PDF/SOR-2016-311.pdf> (last accessed December 5, 2019).

Table 196 summarizes the interactive effects factors for water heating insulation measures.

**Table 196: Interactive Effects Factors for Pipe Insulation and Hot Water Tank Wraps**

| Space Heating         | Energy Interactive Effects During Heating Period | Energy Interactive Effects During Cooling Period | Total Energy Interactive Effects | Peak Demand Interactive Effects |
|-----------------------|--------------------------------------------------|--------------------------------------------------|----------------------------------|---------------------------------|
| Heat Pump Heating     | $-90\% \times 3.8/12 / 1.8 = -15.8\%$            | 0.0%                                             | -15.8%                           | -90%                            |
| Electrical Heating    | $-90\% \times 3.8/12 = -28.5\%$                  | 0.0%                                             | -28.5%                           | -90%                            |
| No Electrical Heating | 0.0%                                             | 0.0%                                             | 0.0%                             | 0%                              |

## Summary

Table 197 summarizes the interactive effects factors established for each water heating measure.

**Table 197: Interactive Effects Factors for Water Heating Measures**

| Measure                                 | Type of Space Heating | Interactive Effects Factors for Energy Savings | Interactive Effects Factors for Peak Demand Savings | Reference                                             |

## 5.4.2 Peak Demand Savings Factors

For hot water tank wraps, energy savings are assumed to occur all the time since the tank always exchanges heat with the space around it. Therefore, peak demand savings for this measure correspond to the average demand savings throughout the year and were established by dividing the energy savings by 8,760 hours, which correspond to a peak demand-to-energy ratio of 0.114 W/kWh.

For other water heating measures, since commercial DHW was not an end use included in the peak demand-to-energy ratios developed by Navigant in the 2016-2018 Demand-side management (DSM) Plan, the Evaluator relied on load shapes from the Illinois TRM to establish a peak demand-to-energy ratio for this end use. Those load shapes rely on simulations to identify what portion of the energy savings is generated during the winter peak, which is defined for Illinois as between 8 a.m. and 11 p.m. on non-holiday weekdays from October to April. While that peak period differs from the one defined in Nova Scotia, those load shapes account for the fact that most water usage happens during the day on weekdays, thus providing a better estimate than spreading savings evenly throughout the year. Therefore, using those load shapes, the Evaluator established a peak demand-to-energy ratio by dividing the energy savings occurring during the peak period by the length of the peak period, as presented in the equations below.

$$\text{Peak Demand-to-energy Ratio} = \frac{\%kWh_{WP} \times 1,000 \text{ kW/W}}{Hours_{WP}}$$

$$Hours_{WP} = (Days_{WP} \times \%Weekdays - Holidays_{WP}) \times \text{Daily Peak Hours}$$

Table 198 lists the parameters and corresponding values applied in the above equations and the resulting peak demand-to-energy ratio.

**Table 198: Peak Demand-to-energy Ratio for Water Heating Measures**

| Parameter                                                    | Symbol                             | Value        | Reference                   |
|--------------------------------------------------------------|------------------------------------|--------------|-----------------------------|
| Portion of Energy Savings Occurring During Winter Peak Hours | $\%kWh_{WP}$                       | 40.5%        | Illinois TRM <sup>249</sup> |

#### Electrical Unitary Energy Savings

The equations below are used to determine the annual unitary savings values for low-flow showerheads. The reduction in hot water consumption is established by the difference between the base and efficient hot water consumption levels, as presented in the second equation.

$$Energy\ Savings\ \left[\frac{kWh}{year}\right] = \%ElectricDHW \times \Delta Gallons\ \left[\frac{gal}{year}\right] \times EPG_{electric}\ \left[\frac{kWh}{gal}\right]$$

$$\Delta Gallons\ \left[\frac{gal}{year}\right] = (GPM_{base} - GPM_{low})\ \left[\frac{gal}{min}\right] \times SH_{time}\ \left[\frac{min}{year}\right] \times \%_{DHW}$$

$$EPG_{Electric}\ \left[\frac{kWh}{gal}\right] = (\rho_{H2O}\ \left[\frac{lb}{ft^3}\right] \times Cp_{H2O}\ \left[\frac{BTU}{lb^{\circ}F}\right] \times \Delta T_{H2O}\ [^{\circ}F] \times UC1\ \left[\frac{kWh}{BTU}\right] \times UC2\ \left[\frac{ft^3}{gal}\right]) / \eta$$

Table 201 below lists the parameters and corresponding values applied in the above equations for low-flow showerheads and the resulting unitary savings values.

**Table 201: Electrical Unitary Energy Savings Values for Low-flow Showerheads**

| Parameter                                                                             | Symbol                                                           | Value      |            |            | Reference                                                                                     |

<sup>253</sup> Iowa Energy Efficiency, *Iowa Energy Efficiency Statewide Technical Reference Manual Version 6.0*, July 23, 2021.

## Electrical Unitary Energy Savings

The equations below are used to calculate the annual unitary savings value for faucet aerators.

$$DHW\ Savings\ \left[\frac{L}{year}\right] = DHW_{base}\ \left[\frac{gal}{year}\right] \times \frac{(q_{base} - q_{low})}{q_{base}} \times UC1\ \left[\frac{L}{gal}\right]$$

$$Unitary\ Savings\ \left[\frac{kWh}{year}\right] = \frac{DHW\ Savings[L] \times Cp\ \left[\frac{lb}{ft^3}\right] \times \rho\ \left[\frac{btu}{lb^{\circ}F}\right] \times \Delta T[^{\circ}F] \times UC2\ \left[\frac{kWh}{btu} \times \frac{ft^3}{L}\right]}{\eta}$$

Table 204 below lists the parameters and values applied in the two above equations for faucet aerators and the resulting unitary savings values.

**Table 204: Electrical Unitary Energy Savings Values for Faucet Aerators**

| Parameter                                           | Symbol                                                              | Value      | Reference                                                                                                         |

## Installation Rates

For SBES faucet aerators, an installation rate of 95% is used based on the value in the 2021 Illinois Statewide TRM.

### (3) Thermostatic Shower Valve

#### Summary

Table 206 presents a summary of the values used to calculate thermostatic shower valve savings. The detailed methodology follows.

**Table 206: Thermostatic Shower Valve Measure Summary**

| Parameter                                          |                                                                                                                      | SBES               |                     |                    |                                                                                        | Reference |

#### Electrical Unitary Energy Savings

The equations below are used to determine the annual unitary savings values for thermostatic shower valves. Energy savings are established by calculating the reduction in hot water usage, as presented in the second equation below.

$$\text{Energy Savings} \left[ \frac{kWh}{\text{year}} \right] = \text{DHW Reduction} \left[ \frac{gal}{\text{year}} \right] \times EPG_{electric} \left[ \frac{kWh}{gal} \right]$$

$$\text{DHW Reduction} \left[ \frac{gal}{\text{year}} \right] = q \left[ \frac{gal}{min} \right] \times \%_{DHW} \times t_w \left[ \frac{min}{shower} \right] \times \frac{SH_{time} \left[ \frac{min}{year} \right]}{t_{shower} \left[ \frac{min}{shower} \right]}$$

$$EPG_{Electric} \left[ \frac{kWh}{gal} \right] = (\rho_{H2O} \left[ \frac{lb}{ft^3} \right] \times Cp_{H2O} \left[ \frac{BTU}{lb^{\circ}F} \right] \times \Delta T_{H2O} [^{\circ}F] \times UC1 \left[ \frac{kWh}{BTU} \right] \times UC2 \left[ \frac{ft^3}{gal} \right]) / \eta$$

Table 207 lists the parameters and corresponding values applied to the two above equations and the resulting unitary savings values for thermostatic shower valves.

**Table 207: Electrical Unitary Energy Savings Values for Thermostatic Shower Valves**

| Interactive Effects Factor for Peak Demand Savings |                                                                           |                                                                                        |

### Electrical Unitary Energy Savings

As presented in Table 209, the annual unitary savings value for pipe insulation was identified through Ontario Power Authority (OPA) 2011<sup>262</sup> values and was established at 12.7 kWh per linear foot. While this value is for residential usage, it was assumed that water heating systems in small businesses would be used for a similar amount of time as a home.

**Table 209: Unitary Energy Savings Value for Pipe Insulation**

| Parameter                                  | SBES |
|--------------------------------------------|------|
| Unitary Energy Savings (per ft) [kWh/year] | 12.7 |

### Installation Rates

The installation rate for SBES pipe insulation is assumed at 100%.

<sup>262</sup> Ontario Power Authority (OPA), *OPA Prescriptive Measures and Assumptions List*, December 2010.

## (5) Hot Water Tank Wraps

### Summary

Table 210 presents a summary of the values used to calculate hot water tank wrap savings. The detailed methodology follows.

**Table 210: Hot Water Tank Wrap Measure Summary**

| Parameter                                          | SBES                                                                  | Reference                                                                              |

| Interactive Effects Factor for Peak Demand Savings |                                                                       |                                                                                        |

## Electrical Unitary Energy Savings

The following equations are used to determine the annual unitary savings associated with hot water tank wraps. The energy savings are equal to the difference in heat losses associated with tank circumference ( $Q_{\text{tank}}$ ) before and after adding the tank wrap ( $Q_{\text{tank+RSI 1.21}}$ ). The heat losses are calculated using the following formulas of heat transfer in an insulated cylinder.

$$R_{\text{layer}} = \frac{\ln(r_e/r_i)}{2\pi k}$$

$$R_{\text{cyl}} = R_{\text{layer1}} + R_{\text{layer2}}$$

$$Q_{\text{cyl}} = \frac{T_i - T_e}{R_{\text{cyl}}} L$$

$$Q_{\text{top}} = \frac{A_{\text{top}} \times (T_i - T_e)}{R_{\text{top}}}$$

$$Q_{\text{total}} = Q_{\text{cyl}} + Q_{\text{top}}$$

$$\text{Energy Savings}_{\text{kWh}} = \frac{(Q_{\text{total}}) \cdot \text{HOU}}{\eta_{\text{heater}}}$$

It is assumed that small businesses use similar hot water tanks as single-family homes. Thus, the calculation considers a typical residential tank with a capacity of 60 imperial gallons and hot water tank wrap with a thermal resistance of 1.21 m<sup>2</sup>·°C/W.

Table 211 below lists the values applied in the above equations to obtain the unitary savings for tank wraps.

**Table 211: Electrical Unitary Energy Savings Values for Hot Water Tank Wraps**

| Parameter                                                                                                                | Symbol                 | Value      | Reference                                                                  |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for heat pump water heaters are calculated based on the metering study used for residential HPWHs, with an adjustment to account for the difference in hot water consumption between residential and commercial buildings. The savings are calculated using the variables defined and listed in the equation and Table 213 below.

$$\Delta kWh = \frac{GPD}{GDP_{res}} \times kWh_{res}$$

$$GPD \text{ (if unknown)} = Capacity \times \frac{Consumption/cap}{365}$$

**Table 213: Electrical Unitary Energy Savings Values for DHW Heat Pump Water Heaters**

| Parameter                                                          | Symbol       | BER-AR, SBES                                                  |                                   |                         | Reference                        |

## Unitary Peak Demand Savings

The unitary peak demand savings for DHW heat pump water heaters are calculated using the variables defined and listed in the equation and Table 215 below, as well as variables from Table 213 above.

$$\Delta kW = \Delta kWh \times PDTER$$

**Table 215: Unitary Peak Demand Savings Values for DHW Heat Pump Water Heaters**

| Parameter                        | Symbol      | BER-AR, SBES                                                                                                                                                                | Reference                            |

## 5.5 Compressed Air

### 5.5.1 Interactive Effects

Interactive effects are assumed to be nil for compressed air projects since compressors are usually in non-conditioned spaces.

### 5.5.2 Peak Demand Savings Factors

For compressed air measures, the peak demand savings factor is assumed to be 77% where it is unknown for the specific project.

### 5.5.3 Adjustment Ratios

For compressed air measures, no adjustment ratios were calculated.

### 5.5.4 Compressed Air Measures

#### (1) Compressed Air Leak Repairs

##### Summary

Table 216 presents a summary of the values used to calculate compressed air leak repair savings. The detailed methodology follows.

**Table 216: Compressed Air Leak Repair Measure Summary**

| Parameter                                          | Custom                                                | Reference                                                 |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for compressed air leak repairs are calculated using the variables defined and listed in the equation and tables below.

$$\text{Unitary Savings [kWh/yr]} = \text{Size of Leak [cfm]} \times \text{Plant Efficiency[kW/(100 cfm)]} \times \text{HOU [h/yr]}$$

**Table 217: Electrical Unitary Energy Savings Values for Compressed Air Leak Repairs**

| Parameter                         | Symbol                             | Value                                                            | Reference                                          |
|-----------------------------------|------------------------------------|------------------------------------------------------------------|----------------------------------------------------|
| Size of Leak [cfm]                | -                                  | Actual                                                           | Project documentation                              |
| Plant Efficiency [kW/100 cfm]     | -                                  | Actual<br>(If unknown, use 19.7 kWh/100 cfm)                     | Project documentation<br>(UE Systems Calculations) |
| Hours of Use [h/yr]               | HOU                                | Actual                                                           | Project documentation                              |
| Unitary Energy Savings [kWh/year] | <i>Unitary Savings</i><br>[kWh/yr] | Calculated based on specification data for each installed system | Calculation                                        |

## Unitary Peak Demand Savings

Unitary peak demand savings for compressed air leak repairs are calculated using the equation below and the variables defined and listed in Table 217 above.

$$\text{Unitary Savings [kW]} = \text{Size of Leak [cfm]} \times \text{Plant Efficiency[kW/(100 cfm)]} \times \text{PCF}$$

**Table 218: Electrical Unitary Peak Demand Values for Compressed Air Leak Repairs**

| Parameter                         | Symbol                         | Value                                                            | Reference             |
|-----------------------------------|--------------------------------|------------------------------------------------------------------|-----------------------|
| Peak Coincidence Factor           | PCF                            | Actual                                                           | Project Documentation |
| Unitary Energy Savings [kWh/year] | <i>Unitary Savings</i><br>[kW] | Calculated based on specification data for each installed system | Calculation           |

## Installation Rates

For Custom measures, the installation rate is assumed to be 100%.

## (2) Cycling Air Dryers

### Summary

Table 219 presents a summary of the values used to calculate cycling air dryer savings. The detailed methodology follows.

**Table 219: Cycling Air Dryer Measure Summary**

| Parameter                                          | BER-AR, SBES                                                                                                                                                   | Reference                                                 |

### Electrical Unitary Energy Savings

The electrical unitary energy savings for cycling air dryers are calculated using the variables defined and listed in the equation<sup>274</sup> and Table 220 below.

$$\Delta kWh = 4 \times hp_{comp} \times 0.0087 \times HOU \times (1 - APC) \times RTD$$

<sup>274</sup> Efficiency Vermont, *Technical Reference User Manual (TRM) Measure Savings Algorithms and Cost Assumption*, March 2015.

**Table 220: Electrical Unitary Energy Savings Values for Cycling Air Dryers**

#### Electrical Unitary Energy Savings

The electrical unitary energy savings for air-entraining air nozzles are calculated using the variables defined and listed in the equation<sup>276</sup> and Table 223 below.

$$\Delta kWh = (CFM_b - CFM_e) \times COMP \times HRS \times \%USE \times QTY$$

<sup>276</sup> Efficiency Vermont, *Technical Reference User Manual (TRM) Measure Savings Algorithms and Cost Assumption*, March 2015.

**Table 223: Electrical Unitary Energy Savings Values for Air-entraining Air Nozzles**

| Parameter                                                             | Symbol       | BER-AR, SBES                                                                                                                                                                                | Reference                                                |

### Electrical Unitary Energy Savings

The electrical unitary energy savings for no-loss drains are calculated using the variables defined and listed in the equation<sup>278</sup> and Table 226 below.

$$\Delta kWh = ALR \times COMP \times OPEN \times AF \times PNC \times QTY$$

<sup>278</sup> Efficiency Vermont, *Technical Reference User Manual (TRM) Measure Savings Algorithms and Cost Assumption*, March 2015.

**Table 226: Electrical Unitary Energy Savings Values for No-loss Drains**

## Unitary Peak Demand Savings

The unitary peak demand savings for no-loss drains are calculated using the variables defined and listed in the equation and Table 228 below, as well as variables from Table 227 above.

$$\Delta kW = \Delta kWh \times PCF / HOU$$

**Table 228: Unitary Peak Demand Savings Values for No-loss Drains**

| Parameter                        | Symbol      | BER-AR, SBES                                                                                                                                                   | Reference               |

## Installation Rates

Installation rates for no-loss drains are estimated at 100%.

## 5.6 Variable Frequency Drives

### 5.6.1 Interactive Effects

Interactive effects are assumed to be nil for variable frequency drive (VFD) projects since this measure is implemented on equipment that is usually in non-conditioned spaces.

### 5.6.2 Peak Demand Savings Factors

For variable frequency drives measures, the methodology used to determine peak demand savings is detailed in the measure-specific subsections below.

### 5.6.3 Adjustment Ratios

For variable frequency drive measures, no adjustment ratios were calculated.

## 5.6.4 Variable Frequency Drive (VFD) Measure

### (1) Variable Frequency Drives for non-HVAC Applications

#### Summary

Table 229 presents a summary of the values used to calculate savings for VFDs installed in non-HVAC applications. The detailed methodology follows.

**Table 229: VFD Measure Summary**

| Parameter                                          | BER-AR                                                                           | Reference                                                 |

#### Electrical Unitary Energy Savings

The electrical unitary energy savings for VFD for non-HVAC applications are calculated using the variables defined and listed in the equations and tables below.

$$Unitary\ Savings\left[\frac{kWh}{yr}\right] = \left(0.746\left[\frac{kW}{hp}\right] \times HP[hp] \times \frac{LF[\%]}{Eff[\%]}\right) \times HOU\left[\frac{h}{yr}\right] \times ESF[\%]$$

$$ESF = \sum_{0\%}^{100\%} (DutyCycle \times PLR_{Baseline}) - \sum_{0\%}^{100\%} (DutyCycle \times PLR_{Eff})$$

**Table 230: Electrical Unitary Energy Savings Values for VFD Pumps and Fans**

| Parameter                                         | Symbol                                                  | Value                                                                           | Reference                                                |

<sup>284</sup> Minnesota Department of Commerce Division of Energy Resources, *State of Minnesota Technical Reference Manual for Energy Conservation Improvement Programs Version 3.1*, January 2020, pp. 691-692.

Example: A process fan with discharge damper controls operates 85% of the time at 75% flow fraction, 5% of the time at 80% flow fraction, and 10% of the time at 95% flow fraction:

$$\sum_{0\%}^{100\%} (DutyCycle \times PLR) = (0.85 \times 0.93) + (0.05 \times 0.97) + (0.10 \times 1.00) = 0.939$$

## Unitary Peak Demand Savings

The unitary peak demand savings for VFD for pumps and fans are calculated using the variables defined and listed in the equation and Table 232 as well as variables from Table 231 above.

$$\begin{aligned} \text{Unitary Peak Demand Savings} \left[ \frac{W}{yr} \right] \\ = \left( 746 \left[ \frac{W}{hp} \right] \times HP[hp] \times \frac{LF[\%]}{Eff[\%]} \right) \times (PLR_{Baseline,FFpeak} - PLR_{Eff,FFpeak}) \end{aligned}$$

In situations where the part load ratio during the peak demand period is unknown, unitary peak demand savings are calculated by multiplying the average demand savings by a peak coincidence factor of 0 or 1 based on business hours and using the equation below.

$$\text{Unitary Peak Demand Savings}[kW] = \left( 0.746 \left[ \frac{kW}{hp} \right] \times HP[hp] \times \frac{LF[\%]}{Eff[\%]} \right) \times ESF[\%] \times PCF$$

**Table 232: Electrical Unitary Peak Demand Values for VFDs for non-HVAC Applications**

| Parameter                                                                         | Symbol                             | Value                                                            | Reference             |
|-----------------------------------------------------------------------------------|------------------------------------|------------------------------------------------------------------|-----------------------|
| Part Load Ratio for the Average Flow Fraction During the Weekday Peak Time Period | $PLR_{Baseline,FFpeak}$            | Based on baseline control and flow fraction                      | Project documentation |
| Part Load Ratio for the Average Flow Fraction During Peak Time Period             | $PLR_{Eff,FFpeak}$                 | Based on VFD control                                             | Project documentation |
| Peak Coincidence Factor                                                           | PCF                                | If business is open during peak period: 1<br>Otherwise: 0        | Project documentation |
| Unitary Peak Demand Savings [W or kWh]                                            | <i>Unitary Peak Demand Savings</i> | Calculated based on specification data for each installed system | Calculation           |

## Installation Rates

Installation rates for VFD for non-HVAC applications are estimated at 100%.

## 5.7 Pool Pumps

### 5.7.1 Interactive Effects

Interactive effects are assumed to be nil for pool pumps projects since this measure is usually implemented in non-conditioned spaces.

## 5.7.2 Peak Demand Savings Factors

For pool pump measures, peak demand savings factors are assumed to be nil since most pumps are installed on outdoor pools that do not operate during the winter peak.

## 5.7.3 Adjustment Ratios

For pool pump measures, no adjustment ratios were calculated.

## 5.7.4 Pool Pump Measure

### (2) ENERGY STAR Pool Pumps

#### Summary

Table 233 presents a summary of the values used to calculate pool pump savings. The detailed methodology follows.

**Table 233: Pool Pump Measure Summary**

| Parameter                                          | BER-AR, SBES                                                                                                           | Reference                                                 |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for pool pumps are calculated using the ENERGY STAR Pool Pump Calculator.<sup>285</sup>

### Installation Rates

Installation rates for pool pumps are assumed to be 100%.

## 5.8 Solar

### 5.8.1 Interactive Effects

Interactive effects are assumed to be nil for solar projects since the equipment involved in such systems is typically installed outdoors.

### 5.8.2 Peak Demand Savings Factors

For solar PV projects, peak demand savings are nil since the solar energy production from those systems coinciding with the peak period is negligible.

### 5.8.3 Adjustment Ratios

For solar measures, no adjustment ratios were calculated.

#### Electrical Unitary Energy Savings

The electrical unitary energy savings for solar PV systems installed in commercial, industrial, and agricultural applications are calculated using the variables defined and listed in the equations and tables below. For each solar PV project, modelled energy production should be obtained either with PV Watts or RETScreen Expert and should include 14% of miscellaneous losses as pre-defined in both modelling tools. Due to inverter capacity, the solar PV systems can only be 100 kW or less.

$$\begin{aligned} \text{Energy Savings per Project [kWh]} \\ = \text{Modelled Energy Production [kWh]} * (1 - \text{Snow Loss Factor}) * \text{Adj. Ratio} \end{aligned}$$

**Table 235: Electrical Unitary Energy Savings Values for Solar PV Systems**

| Parameter                         | Symbol     | Value                                              | Reference                                               |
|-----------------------------------|------------|----------------------------------------------------|---------------------------------------------------------|
| Modelled Energy Production [kWh]  | -          | Actual                                             | Project documentation                                   |
| Snow Loss Factor [%]              | -          | For panel tilt angles $\geq 25^\circ$ : 1%         | Northern Alberta Institute of Technology <sup>286</sup> |
|                                   |            | For panel tilt angles $< 25^\circ$ : 4%            |                                                         |
| Adjustment Ratio                  | Adj. Ratio | Projects modelled with PV Watts: 1.101             | Custom Retrofit evaluation results (2023)               |
|                                   |            | Projects modelled with RETScreen Expert: 0.942     |                                                         |
| Unitary Energy Savings [kWh/year] | -          | Calculated based on data for each installed system | Calculation                                             |

## Installation Rates

For solar photovoltaic systems, the installation rate is assumed to be 100%.

## (2) Solar Domestic Hot Water

### Summary

Table 236 presents a summary of the values used to calculate solar domestic hot water (DHW) savings. The detailed methodology follows.

**Table 236: Solar Domestic Hot Water Measure Summary**

| Parameter                                          | BER-AR                                                                   | Reference                                                 |

| Interactive Effects Factor for Peak Demand Savings | 0%                                                                       | See Subsection 5.8.1                                      |

<sup>286</sup> Northern Alberta Institute of Technology, *Solar Photovoltaic Array Reference Array Report*, March 31, 2016.

## Electrical Unitary Energy Savings

The unitary savings value for solar DHW systems installed through BER-AR is calculated for each system using a custom RETScreen model.

## Unitary Peak Demand Savings

Solar DHW systems provide no peak demand savings because the sun has set during the peak demand period.

## Installation Rates

Installation rates for solar DHW systems are estimated at 100%.

## (3) Solar Air Heating

### Summary

Table 237 presents a summary of the values used to calculate solar air heating savings. The detailed methodology follows.

**Table 237: Solar Air Heating Measure Summary**

| Parameter                                          | BER-AR                                                            | Reference                                                 |

## Electrical Unitary Energy Savings

The unitary savings value for solar air heating systems installed through BER-AR is calculated for each system.

## Installation Rates

Installation rates for solar air heating are estimated at 100%.

## 5.9 Refrigeration

### 5.9.1 Interactive Effects

For refrigeration measures, interactive effects are considered when reduced heat rejection occurs within the refrigerated space, which in turns reduces the electricity consumption of the refrigeration compressor. They are taken into consideration in the unitary electrical energy and peak demand savings equation in the form of a bonus factor, for measures where that applies.

### 5.9.2 Peak Demand Savings Factor

For refrigeration measures, the peak coincidence factor (PCF) is assumed to be 100%, since all equipment is expected to be running continuously, with minor downtime that is addressed in the duty cycle variables, where applicable.

### 5.9.3 Adjustment Ratios

For refrigeration measures, no adjustment ratios were calculated.

## 5.9.4 Refrigeration Measures

### (1) Cooler Night Covers and Display Case Strip Curtains

#### Summary

Table 238 presents a summary of the values used to calculate electrical cooler night cover and display strip curtain savings. The detailed methodology follows.

**Table 238: Cooler Night Cover and Display Strip Curtain Measure Summary**

| Parameter                                          |                                                                                 | BER-AR, SBES                                              | Reference |
|----------------------------------------------------|---------------------------------------------------------------------------------|-----------------------------------------------------------|-----------|
| <b>Measure Description and Identification</b>      |                                                                                 |                                                           |           |
| Measure                                            | Night cover or strip curtain for refrigerated cases, rebated after installation | -                                                         |           |
| Baseline                                           | No night cover or strip curtain                                                 | -                                                         |           |

#### Electrical Unitary Energy Savings

The electrical unitary energy savings for cooler night covers and display strip curtains are calculated using the variables defined and listed in the equation and Table 239 below.<sup>287</sup>

$$Energy\ Savings_{kWh} = (HG \times EF \times CL \times DF) / (EER \times 1,000) \times Usage \times 365$$

<sup>287</sup> Under the 2.8 "Refrigeration" section, if not saying otherwise, the equation comes from Efficiency Vermont, *Technical Reference User Manual (TRM) Measure Savings Algorithms and Cost Assumptions*, March 16, 2015.

**Table 239: Electrical Unitary Savings Values for Cooler Night Covers and Display Strip Curtains**

| Parameter                                                                              | Symbol                              | BER-AR R, SBES                                                                    |                        | Reference                        |

## Unitary Peak Demand Savings

The unitary peak demand savings for cooler night covers and display strip curtains are calculated using the variables defined and listed in the equation and Table 240 below, as well as variables from Table 239 above.

$$Peak\ Demand\ Savings_W = (HG \times EF \times CL \times DF \times PCF) / (EER \times 1000)$$

**Table 240: Unitary Peak Demand Savings Values for Cooler Night Covers and Display Strip Curtains**

### Electrical Unitary Energy Savings

The electrical unitary energy savings for zero-energy doors are calculated using the variables defined and listed in the equation and Table 242 below.

$$\Delta kWh = kW_{door} \times BF \times HOU$$

**Table 242: Electrical Unitary Energy Savings Values for Zero-energy Doors**

| Parameter                                                                             | Symbol             | BER, SBES                                                                      | Reference                        |
|---------------------------------------------------------------------------------------|--------------------|--------------------------------------------------------------------------------|----------------------------------|
| Connected Load of a Typical Reach-in Cooler Door and Frame with Electric Heaters [kW] | kW <sub>door</sub> | 0.131                                                                          | Vermont TRM, 2015 <sup>291</sup> |
| Bonus Factor                                                                          | BF                 | Medium temp (10 - 40F) = 1.22<br>High temp (45 - 65F) = 1.15<br>Average = 1.19 |                                  |
| Hours of Use [h/year]                                                                 | HOU                | 8,760                                                                          |                                  |
| Unitary Energy Savings [kWh/year]                                                     | $\Delta kWh$       | Calculation based on specification data for each rebated unit                  | Calculation                      |

## Unitary Peak Demand Savings

The unitary peak demand savings for zero-energy doors are calculated using the variables defined and listed in the equation and Table 243 below, as well as variables from Table 242 above.

$$\Delta kW = kW_{door} \times BF \times PCF$$

**Table 243: Unitary Peak Demand Savings Values for Zero-energy Doors**

| Parameter                       | Symbol      | BER-AR, SBES                                                  | Reference               |
|---------------------------------|-------------|---------------------------------------------------------------|-------------------------|
| Peak Coincidence Factor         | PCF         | 1                                                             | As per Subsection 5.9.2 |
| Unitary Peak Demand Savings [W] | $\Delta kW$ | Calculation based on specification data for each rebated unit | Calculation             |

## Installation Rates

Installation rates for zero-energy doors are assumed to be 100%.

<sup>291</sup> Efficiency Vermont, *Technical reference User Manual*, March 16, 2015.

### (3) Door Heater Controls

#### Summary

Table 244 presents a summary of the values used to calculate electrical door heater control savings. The detailed methodology follows.

### Electrical Unitary Energy Savings

The electrical unitary energy savings for evaporator fan motor controls are calculated using the variables defined and listed in the equation and Table 248 below.

$$\Delta kWh = \left( (kW_{evap} \times n_{fans} \times DC_{evap}) - kW_{circ} \right) \times (1 - DC_{comp}) \times BF \times HOU$$

**Table 248: Electrical Unitary Energy Savings Values for Evaporator Fan Motor Controls**

## Unitary Peak Demand Savings

The unitary peak demand savings for evaporator fan motor controls are calculated using the variables defined and listed in the equation and Table 249 below, as well as variables from Table 248 above.

$$\Delta kW = \left( (kW_{evap} \times n_{fans} \times DC_{evap}) - kW_{circ} \right) \times (1 - DC_{comp}) \times BF \times PCF$$

**Table 249: Unitary Peak Demand Savings Values for Cooler Night Covers and Display Strip Curtains**

| Parameter                       | Symbol      | BER-AR, SBES                                                  | Reference               |
|---------------------------------|-------------|---------------------------------------------------------------|-------------------------|
| Peak Coincidence Factor         | PCF         | 1                                                             | As per Subsection 5.9.2 |
| Unitary Peak Demand Savings [W] | $\Delta kW$ | Calculation based on specification data for each rebated unit | Calculation             |

## Installation Rates

Installation rates for evaporator fan motor controls are estimated at 100%.

<sup>293</sup> Efficiency Vermont, *Technical Reference Manual (TRM): Program Year 2013*.

## (5) Intelligent Freezer Defrost Controls

### Summary

Table 250 presents a summary of the values used to calculate electrical intelligent freezer defrost control savings. The detailed methodology follows.

**Table 250: Intelligent Freezer Defrost Control Measure Summary**

### Electrical Unitary Energy Savings

The electrical unitary energy savings for intelligent freezer defrost control are calculated using the variables defined and listed in the equation and Table 251 below.

$$\Delta kWh = n_{fans} \times kW_{DE} \times SVG \times BF \times FLH$$

**Table 251: Electrical Unitary Energy Savings Values for Intelligent Freezer Defrost Controls**

| Parameter                                 | Symbol       | BER-AR, SBES                                                  | Reference                        |
|-------------------------------------------|--------------|---------------------------------------------------------------|----------------------------------|
| Number of Evaporator Fans                 | nfans        | Actual                                                        | Use information in TS            |
| kW of Defrost Element per Evaporator Fan  | kWDE         | 0.9                                                           | Vermont TRM, 2015 <sup>294</sup> |
| Percent of Defrost Cycle Saved by Control | SVG          | 30%                                                           | Vermont TRM, 2015                |
| Bonus Factor                              | BF           | 1.5 for low temp                                              | Vermont TRM, 2015                |
| Average Full Load Defrost Hours           | FLH          | 487                                                           | Vermont TRM, 2015                |

## Unitary Peak Demand Savings

The unitary peak demand savings for intelligent freezer defrost control are calculated using the variables defined and listed in the equation and Table 252 below, as well as variables from Table 251 above.

$$\Delta kW = n_{fans} \times kW_{DE} \times SVG \times BF \times PCF$$

**Table 252: Unitary Peak Demand Savings Values for Intelligent Freezer Defrost Controls**

| Parameter                       | Symbol      | BER-AR, SBES                                                  | Reference            |
|---------------------------------|-------------|---------------------------------------------------------------|----------------------|
| Peak Coincidence Factor         | PCF         | 1                                                             | See Subsection 5.9.2 |
| Unitary Peak Demand Savings [W] | $\Delta kW$ | Calculation based on specification data for each rebated unit | Calculation          |

## Installation Rates

Installation rates for intelligent freezer defrost control are estimated at 100%.

## Electrical Unitary Energy Savings

The electrical unitary energy savings for refrigeration economizer are calculated using the variables defined and listed in the equation and Table 262 below.

With fan control installed

$$\Delta kWh = (HP \times kWh_{cond}) + \left( (kW_{evap} \times n_{fans}) - kW_{circ} \right) \times HRS \times DC_{comp} \times BF - (kW_{econ} \times DC_{econ} \times HOU)$$

Without fan control installed

$$\Delta kWh = (HP \times kWh_{cond}) + (kW_{econ} \times DC_{econ} \times HOU)$$

**Table 262: Electrical Unitary Energy Savings Values for Refrigeration Economizers**

| Parameter                                                                                      | Symbol       | BER-AR, SBES                                                         | Reference                                                                                                                                                                                             |

## Unitary Peak Demand Savings

The unitary peak demand savings for refrigeration economizer are calculated using the variables defined and listed in the equation and Table 263 below, as well as variables from Table 262 above.

$$\Delta kW = \Delta kWh \times PCF / HOU$$

**Table 263: Unitary Peak Demand Savings Values for Refrigeration Economizers**

| Parameter                       | Symbol      | BER-AR, SBES                                                  | Reference            |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for brushless DC motors are calculated using the variables defined and listed in the equation<sup>303</sup> and Table 265 below.

$$\Delta kWh = \left( \frac{kW_{output}}{\eta_{base}} - \frac{kW_{output}}{\eta_{ee}} \right) \times HOU \times DC \times LF \times \left( 1 + \frac{1}{COP} \right)$$

**Table 265: Electrical Unitary Energy Savings Values for Brushless DC Motors**

| Parameter                         | Symbol        | Value for BER-AR and SBES                                          | Reference                                |
|-----------------------------------|---------------|--------------------------------------------------------------------|------------------------------------------|

### Electrical Unitary Energy Savings

The electrical unitary energy savings for refrigerated vending machine controllers are calculated using the variables defined and listed in the equation<sup>306</sup> and Table 268 below.

$$\Delta kWh = kW_{rated} \times HOU \times SAVE \times QTY$$

<sup>306</sup> Massachusetts, *Technical Reference User Manual (TRM) for Estimating Savings from Energy Efficiency Measures*, October 2012.

**Table 268: Electrical Unitary Energy Savings Values for Refrigerated Vending Machine Controllers**

| Parameter                                          | Symbol              | BER-AR, SBES                                                                             | Reference                              |

| Unitary Energy Savings [kWh/year]                  | $\Delta kWh$        | Calculation based on specification data for each rebated unit                            | Calculation                            |

## Unitary Peak Demand Savings

The unitary peak demand savings for refrigerated vending machine controllers are calculated using the variables defined and listed in the equation and Table 269 below, as well as variables from Table 268 above.

$$\Delta kW = kW_{rated} \times SAVE \times QTY \times PCF$$

**Table 269: Unitary Peak Demand Savings Values for Refrigerated Vending Machine Controllers**

| Parameter                       | Symbol      | BER-AR, SBES                                                  | Reference               |
|---------------------------------|-------------|---------------------------------------------------------------|-------------------------|
| Peak Coincidence Factor         | PCF         | 1                                                             | As per Subsection 5.9.2 |
| Unitary Peak Demand Savings [W] | $\Delta kW$ | Calculation based on specification data for each rebated unit | Calculation             |

## Installation Rates

Installation rates for refrigerated vending machine controllers are estimated at 100%.

## 5.10 Agriculture

### 5.10.1 Interactive Effects

Interactive effects are assumed to be nil for agriculture measures since they are usually located in spaces that are not heated or cooled electrically.

### 5.10.2 Peak Demand Savings Factors

For agriculture measures, peak demand savings are determined by multiplying the wattage by a PCF value of 84%, which was established as part of the 2015 evaluation of BER.<sup>308</sup>

<sup>307</sup> Mass Save, *Massachusetts Technical Reference Manual*, 2012.

<sup>308</sup> Econoler, *Business Energy Rebates 2015 DSM Evaluation*, Report presented to Efficiency Nova Scotia, 2016.

### 5.10.3 Adjustment Ratios

The adjustment ratios in Table 270 for were established as part of the 2022 can be extrapolated for all Agricultural measures in BER-AR. No adjustment ratios were calculated for SBES.

**Table 270: Agriculture Gross Savings Adjustments**

| Path and Measure Category                  | Energy Savings   |                 | Peak Demand Savings |                 |

### 5.10.4 Agriculture Measures

#### (1) High Volume Low Speed Fans

##### Summary

Table 271 presents a summary of the values used to calculate high volume low speed fan savings. The detailed methodology follows.

**Table 271: High Volume Low Speed Fan Measure Summary**

| Parameter                                          | BER-AR                                                                                                    | SBES | Reference                                                 |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------|------|-----------------------------------------------------------|
| Measure Description and Identification             |                                                                                                           |      |                                                           |
| Measure                                            | CSA / cUL rated High Volume Low Speed (HVLS) fans for agricultural facilities, rebated after installation | -    |                                                           |
| Baseline                                           | Must replace existing circulation fans (unless building is new construction)                              | -    |                                                           |
| General Parameters                                 |                                                                                                           |      |                                                           |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for high volume low speed fans are calculated using the variables defined and listed in the equation<sup>309</sup> and Table 272 below.

$$\Delta kWh = (P_b \times QTY_b - P_e \times QTY_e) \times HOU / 1,000$$

**Table 272: Electrical Unitary Energy Savings Values for High Volume Low Speed Fans**

| Parameter                         | Symbol           | BER-AR, SBES                                                                                                                 | Reference                                                                          |
|-----------------------------------|------------------|------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| Power of the Baseline Fans [W]    | P <sub>b</sub>   | Actual or based on fan size (ft)<br>>= 16 and <18 = 4,497<br>>= 18 and <20 = 5,026<br>>= 20 and <24 = 5,555<br>>= 24 = 6,613 | Use information in TS<br>Default values from Pennsylvania TRM, 2019 <sup>310</sup> |
| Quantity of Baseline Fans         | QTY <sub>b</sub> | Actual or if not using actual fan power, assume QTY <sub>b</sub> is equal to QTY <sub>e</sub>                                | Use information in TS                                                              |
| HVLS Power Consumption, [W]       | P <sub>e</sub>   | Actual or based on fan size (ft)<br>>= 16 and <18 = 761<br>>= 18 and <20 = 850<br>>= 20 and <24 = 940<br>>= 24 = 1,119       | Use information in TS<br>Default values from Pennsylvania TRM, 2019                |
| Total Quantity of New HVLS Fans   | QTY <sub>e</sub> | Actual or if not using actual fan power, assume QTY <sub>b</sub> is equal to QTY <sub>e</sub>                                | Use information in TS                                                              |
| Hours of Use [h/year]             | HOU              | Actual or 2928                                                                                                               | Use information in TS                                                              |
| Unitary Energy Savings [kWh/year] | ΔkWh             | Calculation based on specification data for each rebated unit                                                                | Calculation                                                                        |

## Unitary Peak Demand Savings

The unitary peak demand savings for high volume low speed fans are calculated using the variables defined and listed in the equation and Table 273 below, as well as variables from Table 272 above.

$$\Delta kW = (P_b \times QTY_b - P_e \times QTY_e) \times PCF / 1000$$

**Table 273: Unitary Peak Demand Savings Values for High Volume Low Speed Fans**

| Parameter                       | Symbol | BER-AR, SBES                                                  | Reference                |
|---------------------------------|--------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF    | 0.84                                                          | As per Subsection 5.10.2 |
| Unitary Peak Demand Savings [W] | ΔkW    | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for high volume low speed fans in SBES are estimated at 100%.

<sup>309</sup> Pennsylvania PUC, *Technical Reference Manual (TRM) Volume 3*, August 2019.

<sup>310</sup> Pennsylvania Public Utility Commission, *Technical Reference Manual Volume 3: Commercial and Industrial Measures*, April 2019, p.308.

## (2) Energy Efficient Ventilation and Circulation Fans

### Summary

Table 274 presents a summary of the values used to calculate energy efficient ventilation and circulation fan savings. The detailed methodology follows.

**Table 274: Energy Efficient Ventilation and Circulation Fan Measure Summary**

| Parameter                                          | BER-AR                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | SBES | Reference                                                 |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for energy efficient ventilation & circulation fans are calculated using the variables defined and listed in the equation and Table 275 below.

$$\Delta kWh = \left( \frac{AF_b}{ER_b} \times Qty_b - \frac{AF_e}{ER_e} \times Qty_e \right) \times HOU / 1,000$$

**Table 275: Electrical Unitary Energy Savings Values for Energy Efficient Ventilation and Circulation Fans**

| Parameter                               | Symbol           | BER-AR, SBES                                                                            |                                                                                         | Reference                                                      |

## Unitary Peak Demand Savings

The unitary peak demand savings for energy efficient ventilation & circulation fans are calculated using the variables defined and listed in the equation and Table 276 below, as well as variables from Table 275 above.

$$\Delta kW = \left( \frac{AF_b}{ER_b} \times Qty_b - \frac{AF_e}{ER_e} \times Qty_e \right) \times PCF / 1,000$$

**Table 276: Unitary Peak Demand Savings Values  
for Energy Efficient Ventilation and Circulation Fans**

| Parameter                       | Symbol      | BER-AR, SBES                                                  | Reference                |
|---------------------------------|-------------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF         | 0.84                                                          | As per Subsection 5.10.2 |

## Installation Rates

Installation rates for energy efficient ventilation & circulation fans in SBES are assumed to be 100%.

## (3) Dual and Natural Ventilation

### Summary

Table 277 presents a summary of the values used to calculate dual and natural ventilation savings. The detailed methodology follows.

**Table 277: Dual and Natural Ventilation Measure Summary**

| Parameter                              | BER-AR                                                                                                                                                                                                                                                                                                                                                                                                                                                 | SBES | Reference                                  |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------------------------------------------|
| Measure Description and Identification |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |      |                                            |
| Measure                                | Both natural and dual ventilation systems that meet the following criteria are eligible, rebated after installation:<br>- Natural Ventilation – No mechanical ventilation present. All ventilation provided by chimneys and sidewall openings (with curtains or panels)<br>- Dual Ventilation – Mechanical ventilation to modulate exhaust in winter months only<br>- Eligible facility types: dairy cows, swine, layers, broilers, turkeys, and sheep | -    |                                            |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for dual & natural ventilation are calculated using the variables defined and listed in the equation and Table 278 below.

$$\Delta kWh = LC \times ARL \times \frac{1}{ER} \times SF \times HOU \times QTY / 1,000$$

**Table 278: Electrical Unitary Energy Savings Values for Dual and Natural Ventilation**

## Unitary Peak Demand Savings

The unitary peak demand savings for dual & natural ventilation are calculated using the variables defined and listed in the equation and Table 279 below, as well as variables from Table 278 above.

$$\Delta kW = LC \times ARL \times \frac{1}{ER} \times SF \times PCF \times QTY / 1,000$$

**Table 279: Unitary Peak Demand Savings Values for Dual and Natural Ventilation**

| Parameter                       | Symbol      | BER-AR, SBES                                                  | Reference                |
|---------------------------------|-------------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF         | 0.84                                                          | As per Subsection 5.10.2 |
| Unitary Peak Demand Savings [W] | $\Delta kW$ | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for dual & natural ventilation in SBES are assumed to be 100%.

## (4) Zero-energy and Low-energy Livestock Waterers

### Summary

Table 280 presents a summary of the values used to calculate zero-energy and low-energy livestock waterer savings. The detailed methodology follows.

**Table 280: Zero-energy and Low-energy Livestock Waterer Measure Summary**

| Parameter                                          | BER-AR                                                                                                                        | SBES | Reference                                                 |

### Electrical Unitary Energy Savings

The electrical unitary energy savings for agriculture heat pads are calculated using the variables defined and listed in the equation and Table 284 below.

$$\Delta kWh = (P_b \times Qty_b - P_e \times Qty_e) \times HOU / 1,000$$

**Table 284: Electrical Unitary Energy Savings Values for Agriculture Heat Pads**

| Parameter                         | Symbol       | BER-AR, SBES                                                  | Reference                                                                                                                   |

### Electrical Unitary Energy Savings

The electrical unitary energy savings for tractor engine block heater timers are calculated using the variables defined and listed in the equation and Table 287 below.

$$\Delta kWh = P_{heater} \times (HOU_b - HOU_e) \times DAYS / 1,000$$

**Table 287: Electrical Unitary Energy Savings Values for Tractor Engine Block Heater Timers**

| Parameter                                    | Symbol       | BER-AR, SBES                                                  | Reference                                                                 |
|----------------------------------------------|--------------|---------------------------------------------------------------|---------------------------------------------------------------------------|
| Power Consumption of Engine Block Heater [W] | $P_{heater}$ | Actual                                                        | Use information in TS                                                     |
| Baseline Hours of Use [h/day]                | $HOU_b$      | Actual or 10                                                  | Use information in TS<br><u>Default:</u> New York 2024 TRM <sup>319</sup> |

| Days per Year that Heater Is Used            | DAYS         | Actual or 120                                                 | Use information in TS<br><u>Default:</u> No reference                     |
| Unitary Energy Savings [kWh/year]            | $\Delta kWh$ | Calculation based on specification data for each rebated unit | Calculation                                                               |

## Unitary Peak Demand Savings

The unitary peak demand savings for tractor engine block heater timer are calculated using the variables defined and listed in the equation and Table 288 below, as well as variables from Table 287 above.

$$\Delta kW = P_{heater} \times PCF / 1,000$$

**Table 288: Unitary Peak Demand Savings Values for Tractor Engine Block Heater Timers**

| Parameter                       | Symbol      | BER-AR, SBES                                                  | Reference                |
|---------------------------------|-------------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF         | 0.84                                                          | As per Subsection 5.10.2 |
| Unitary Peak Demand Savings [W] | $\Delta kW$ | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for tractor engine block heater timer in SBES are assumed to be 100%.

### Electrical Unitary Energy Savings

The electrical unitary energy savings for dairy scroll compressors are calculated using the variables defined and listed in the equation<sup>321</sup> and Table 290 below.

$$\Delta kWh = \frac{\left( \frac{1}{EER_b} - \frac{1}{EER_e} \right) \times HOU \times DAYS \times COWS \times Lb_{milk} \times c_{p,milk} \times \Delta T}{1,000}$$

<sup>321</sup> Illinois Energy Efficiency, *Illinois Statewide Technical Reference Manual – Volume 2: Commercial and Industrial Measure*, September 22, 2023.

**Table 290: Electrical Unitary Energy Savings Values for Dairy Scroll Compressors**

| Parameter                                                  | Symbol       | BER-AR, SBES                                                    | Reference                                                                                        |

## Unitary Peak Demand Savings

The unitary peak demand savings for dairy scroll compressors are calculated using the variables defined and listed in the equation and Table 291 below, as well as variables from Table 290 above.

$$\Delta kW = (\Delta kWh / HOU) \times PCF$$

**Table 291: Unitary Peak Demand Savings Values for Dairy Scroll Compressors**

| Parameter                       | Symbol      | BER-AR, SBES                                                  | Reference                |
|---------------------------------|-------------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF         | Actual                                                        | As per Subsection 5.10.2 |
| Unitary Peak Demand Savings [W] | $\Delta kW$ | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for dairy scroll compressors for SBES are assumed to be 100%.

### Electrical Unitary Energy Savings

The electrical unitary energy savings for heat reclaimer units are calculated using the variables defined and listed in the equation and Table 293 below.

$$\Delta kWh = COWS \times \frac{MILK}{COW} \times (U_{warm} - U_{cold}) \times \frac{1}{3,600} \times \frac{EFF_{hx}}{EFF_{wh}} * 1.0989$$

**Table 293: Electrical Unitary Energy Savings Values for Heat Reclaimer Units**

| Parameter                                                                               | Symbol       | BER-AR, SBES                                                                                                                                                                      | Reference                                                                                        |

## Unitary Peak Demand Savings

The unitary peak demand savings for heat reclaimer units are calculated using the variables defined and listed in the equation and Table 294 below, as well as variables from Table 293 above.

$$\Delta kW = (\Delta kWh / HOU) \times PCF$$

## Electrical Unitary Energy Savings

The electrical unitary energy savings for milk pre-cooler are calculated using the variables defined and listed in the equation and Table 296 below.

$$\Delta kWh = COWS \times \frac{MILK}{COW} \times (T_{warm} - T_{cold}) \times \frac{1}{3,600} \times c \times \left(\frac{\rho}{COP}\right) \times QTY$$

**Table 296: Electrical Unitary Energy Savings Values for Milk Pre-Coolers**

## Unitary Peak Demand Savings

The unitary peak demand savings for milk pre-cooler are calculated using the variables defined and listed in the equation and Table 297 below, as well as variables from Table 296 above.

$$\Delta kW = (\Delta kWh/HOU) \times PCF$$

## Electrical Unitary Energy Savings

The electrical unitary energy savings for VFD for milk vacuum pump are calculated using the variables defined and listed in the equation and Table 299 below.

$$\Delta kWh = \left( HP \times 0.746 \times \frac{1}{EFF_{motor}} \times LF \right) \times (1 - MSF) \times HOU$$

**Table 299: Electrical Unitary Energy Savings Values for Milk Vacuum Pumps**

| Parameter                          | Symbol               | BER-AR, SBES                                                                   | Reference             |
|------------------------------------|----------------------|--------------------------------------------------------------------------------|-----------------------|
| Horsepower of Connected Pump Motor | HP                   | Actual                                                                         | Use information in TS |
| Conversion from hp to kW           | -                    | 0.746                                                                          | Convention            |

## Unitary Peak Demand Savings

The unitary peak demand savings for VFD for milk vacuum pump are calculated using the variables defined and listed in the equation and Table 300 below, as well as variables from Table 299 above.

$$\Delta kW = \left( HP \times 0.746 \times \frac{1}{EFF_{motor}} \times LF \right) \times (1 - MSF) \times PCF$$

**Table 300: Unitary Peak Demand Savings Values for Milk Vacuum Pumps**

| Parameter                       | Symbol      | BER-AR, SBES                                                  | Reference                |
|---------------------------------|-------------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF         | 0.84                                                          | As per Subsection 5.10.2 |
| Unitary Peak Demand Savings [W] | $\Delta kW$ | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for VFD for milk vacuum pumps in SBES are assumed to be 100%.

## (11) VFD Milk Transfer Pumps

### Summary

Table 301 presents a summary of the values used to calculate VFD milk transfer pump savings. The detailed methodology follows.

**Table 301: VFD Milk Transfer Pump Measure Summary**

| Parameter                                          | BER-AR                                                                                                            | SBES | Reference                                                 |

### Electrical Unitary Energy Savings

The electrical unitary energy savings for VFD milk transfer pump are calculated using the variables defined and listed in the equation and Table 302 below.

$$\Delta kWh = EF \times COWS$$

**Table 302: Electrical Unitary Energy Savings Values for VFD Milk Transfer Pumps**

| Parameter                                                                                | Symbol       | BER-AR, SBES                                                  | Reference                         |
|------------------------------------------------------------------------------------------|--------------|---------------------------------------------------------------|-----------------------------------|
| Energy Factor - Estimate of Energy Offset by Using VFD Milk Transfer Pump per Cow Milked | EF           | 33.945                                                        | Massachusetts Farm Energy Program |
| Average Number of Cows Milked per Day                                                    | COWS         | Actual                                                        | Use information in TS             |
| Unitary Energy Savings [kWh/year]                                                        | $\Delta kWh$ | Calculation based on specification data for each rebated unit | Calculation                       |

## Unitary Peak Demand Savings

The unitary peak demand savings for VFD milk transfer pump are calculated using the variables defined and listed in the equation and Table 303 below, as well as variables from Table 302 above.

$$\Delta kW = (EF \times COWS \times PCF) / HOU$$

**Table 303: Unitary Peak Demand Savings Values for VFD Milk Transfer Pumps**

| Parameter                       | Symbol      | BER-AR, SBES                                                  | Reference                                                                  |
|---------------------------------|-------------|---------------------------------------------------------------|----------------------------------------------------------------------------|
| Peak Coincidence Factor         | PCF         | 0.84                                                          | As per Subsection 5.10.2                                                   |
| Hours of Use [h/year]           | HOU         | Actual or 2,920                                               | Use information in TS<br><u>Default:</u> Minnesota 2025 TRM <sup>335</sup> |
| Unitary Peak Demand Savings [W] | $\Delta kW$ | Calculation based on specification data for each rebated unit | Calculation                                                                |

## Installation Rates

Installation rates for VFD milk transfer pumps in SBES are assumed to be 100%.

### 5.11 Commercial Kitchen Equipment

#### 5.11.1 Interactive Effects

Interactive effects are assumed to be nil for kitchen measures since they are usually located in spaces that are not heated or cooled electrically.

#### 5.11.2 Peak Demand Savings Factor

For kitchen measures, peak demand savings are determined by multiplying the wattage by a PCF value of 68%, which was established as part of the 2015 evaluation of BER.<sup>336</sup> Freezers and refrigerators have a PCF of 100%

#### 5.11.3 Adjustment Ratios

For kitchen measures, no adjustment ratios were calculated.

#### Electrical Unitary Energy Savings

The electrical unitary energy savings for dishwashers are calculated using the ENERGY STAR Commercial Kitchen Calculator using the parameters in Table 305 below.

**Table 305: Electrical Unitary Energy Savings Values for Dishwashers**

| Parameter                                                   | Symbol | BER-AR R, SBES                                                 | Reference                                 |
|-------------------------------------------------------------|--------|----------------------------------------------------------------|-------------------------------------------|
| Annual Days of Operation [days/year]                        | DAYS   | Actual                                                         | Measure specific - use information in TS  |
| Average Daily Operation [hours/day]                         | HOU    | Actual                                                         | Measure specific - use information in TS  |
| Racks Washed per Day                                        | -      | Actual                                                         | Measure specific - use information in TS  |
| Idle Energy Rate of Efficient Equipment [kW]                | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Water Use of Efficient Equipment [gallons/rack]             | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Typical Total Wash Time in Minutes                          | -      | Actual                                                         | Measure specific - use information in TS  |
| Water Heating Energy for Building Water Heater [kWh/gallon] | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Water Heating Energy for Booster Water Heater [kWh/gallon]  | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Energy Savings [kWh]                                        | ES     | Calculated using the ENERGY STAR Commercial Kitchen Calculator | ENERGY STAR Commercial Kitchen Calculator |

## Unitary Peak Demand Savings

The unitary peak demand savings for dishwashers are calculated using the variables defined and listed in the equation and Table 306 below, as well as variables from Table 305 above.

$$Peak\ Demand\ Savings_{kW} = (ES \times PCF) / (HOU \times DAYS)$$

**Table 306: Unitary Peak Demand Savings Values for Dishwashers**

| Parameter                       | Symbol                       | BER-AR, SBES                                                  | Reference                |
|---------------------------------|------------------------------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF                          | Actual or 0.68                                                | As per Subsection 5.11.2 |
| Unitary Peak Demand Savings [W] | $Peak\ Demand\ Savings_{kW}$ | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for dishwashers are assumed to be 100%.

## (2) Freezers/Refrigerators

### Summary

Table 307 presents a summary of the values used to calculate electrical freezer/refrigerator savings. The detailed methodology follows.

**Table 307: Freezer/Refrigerator Measure Summary**

| Parameter                                          | BER-AR, SBES                                                                      | Reference                                                 |
|----------------------------------------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------|

### Electrical Unitary Energy Savings

The electrical unitary energy savings for freezers and refrigerators are calculated using the ENERGY STAR Commercial Kitchen Calculator using the parameters in Table 308 below.

**Table 308: Electrical Unitary Energy Savings Values for Freezers/Refrigerators**

| Parameter                                                                  | Symbol | BER-AR R, SBES                                                 | Reference                                 |
|----------------------------------------------------------------------------|--------|----------------------------------------------------------------|-------------------------------------------|
| Annual Days of Operation [days/year]                                       | DAYS   | Actual                                                         | Measure specific - use information in TS  |
| Average Daily Operation [hours/day]                                        | HOU    | Actual                                                         | Measure specific - use information in TS  |
| Interior Volume [ft3]                                                      | -      | Actual                                                         | Measure specific - use information in TS  |
| Energy Use (or daily energy consumption) for Efficient Equipment [kWh/day] | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Energy Savings [kWh]                                                       | ES     | Calculated using the ENERGY STAR Commercial Kitchen Calculator | ENERGY STAR Commercial Kitchen Calculator |

## Unitary Peak Demand Savings

The unitary peak demand savings for freezer/refrigerator are calculated using the variables defined and listed in the equation and Table 309 below, as well as variables from Table 308 above.

$$\text{Peak Demand Savings}_{kW} = (ES \times PCF) / (HOU \times DAYS)$$

**Table 309: Unitary Peak Demand Savings Values for Freezers/Refrigerators**

| Parameter                       | Symbol                                  | BER-AR, SBES                                                  | Reference                |
|---------------------------------|-----------------------------------------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF                                     | 1                                                             | As per Subsection 5.11.2 |
| Unitary Peak Demand Savings [W] | <i>Peak Demand Savings<sub>kW</sub></i> | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for freezers/refrigerators are assumed to be 100%.

### (3) Fryer

#### Summary

Table 310 presents a summary of the values used to calculate electrical fryer savings. The detailed methodology follows.

**Table 310: Fryer Measure Summary**

| Parameter                                          | BER-AR, SBES                                                  | Reference                                                 |
|----------------------------------------------------|---------------------------------------------------------------|-----------------------------------------------------------|
| <b>Measure Description and Identification</b>      |                                                               |                                                           |
| Measure                                            | ENERGY STAR® rated fryer, rebated after installation          | -                                                         |
| Baseline                                           | Standard electric fryer                                       | -                                                         |
| <b>General Parameters</b>                          |                                                               |                                                           |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for fryers are calculated using the ENERGY STAR Commercial Kitchen Calculator using the parameters in Table 311 below.

**Table 311: Electrical Unitary Energy Savings Values for Fryers**

| Parameter                                                                      | Symbol | BER-AR R, SBES                                                 | Reference                                 |
|--------------------------------------------------------------------------------|--------|----------------------------------------------------------------|-------------------------------------------|
| Annual Days of Operation [days/year]                                           | DAYS   | Actual                                                         | Measure specific - use information in TS  |
| Average Daily Operation [hours/day]                                            | HOU    | Actual                                                         | Measure specific - use information in TS  |
| Size of Fryer                                                                  | -      | Actual (options are standard or large)                         | Measure specific - use information in TS  |
| Food Cooked per Day [pounds]<br>Pro-rate Based on HRS (if HRS do not equal 16) | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Shortening Capacity [lbs]                                                      | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Cooking Energy Efficiency of Efficient Fryer [%]                               | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Energy Use (or idle energy rate) of Efficient Fryer [Btu/hr]                   | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Energy Savings [kWh]                                                           | ES     | Calculated using the ENERGY STAR Commercial Kitchen Calculator | ENERGY STAR Commercial Kitchen Calculator |

## Unitary Peak Demand Savings

The unitary peak demand savings for fryers are calculated using the variables defined and listed in the equation and Table 312 below, as well as variables from Table 311 above.

$$Peak\ Demand\ Savings_{kW} = (ES \times PCF) / (HOU \times DAYS)$$

**Table 312: Unitary Peak Demand Savings Values for Fryers**

| Parameter                       | Symbol                       | BER-AR, SBES                                                  | Reference                |
|---------------------------------|------------------------------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF                          | Actual or 0.68                                                | As per Subsection 5.11.2 |
| Unitary Peak Demand Savings [W] | $Peak\ Demand\ Savings_{kW}$ | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for fryers are assumed to be 100%.

## (4) Griddles

### Summary

Table 313 presents a summary of the values used to calculate electrical griddles savings. The detailed methodology follows.

**Table 313: Griddle Measure Summary**

| Parameter                                          | BER-AR, SBES                                                  | Reference                                                 |
|----------------------------------------------------|---------------------------------------------------------------|-----------------------------------------------------------|
| <b>Measure Description and Identification</b>      |                                                               |                                                           |
| Measure                                            | ENERGY STAR® rated griddle, rebated after installation        | -                                                         |

### Electrical Unitary Energy Savings

The electrical unitary energy savings for griddles are calculated using the ENERGY STAR Commercial Kitchen Calculator using the parameters in Table 314 below.

**Table 314: Electrical Unitary Energy Savings Values for Griddles**

| Parameter                                                                      | Symbol | BER-AR R, SBES                                                 | Reference                                 |
|--------------------------------------------------------------------------------|--------|----------------------------------------------------------------|-------------------------------------------|
| Annual Days of Operation [days/year]                                           | DAYS   | Actual                                                         | Measure specific - use information in TS  |
| Average Daily Operation [hours/day]                                            | HOU    | Actual                                                         | Measure specific - use information in TS  |
| Width of Griddle [ft]                                                          | -      | Actual                                                         | Measure specific - use information in TS  |
| Depth of Griddle [ft]                                                          | -      | Actual                                                         | Measure specific - use information in TS  |
| Food Cooked per Day [pounds]<br>Pro-rate Based on HRS (if HRS do not equal 12) | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Cooking Energy Efficiency of Efficient Griddle [%]                             | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Energy Use (or normalized idle energy) of Efficient Griddle [Btu/hr/sqft]      | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Energy Savings [kWh]                                                           | ES     | Calculated using the ENERGY STAR Commercial Kitchen Calculator | ENERGY STAR Commercial Kitchen Calculator |

## Unitary Peak Demand Savings

The unitary peak demand savings for griddles are calculated using the variables defined and listed in the equation and Table 315 below, as well as variables from Table 314 above.

$$Peak\ Demand\ Savings_{kW} = (ES \times PCF) / (HOU \times DAYS)$$

**Table 315: Unitary Peak Demand Savings Values for Griddles**

| Parameter                       | Symbol                                  | BER-AR, SBES                                                  | Reference                |
|---------------------------------|-----------------------------------------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF                                     | Actual or 0.68                                                | As per Subsection 5.11.2 |
| Unitary Peak Demand Savings [W] | <i>Peak Demand Savings<sub>kW</sub></i> | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for griddles are assumed to be 100%.

## (5) Hot Food Holding Cabinets

### Summary

Table 316 presents a summary of the values used to calculate electrical hot food holding cabinets savings. The detailed methodology follows.

**Table 316: Hot Food Holding Cabinet Measure Summary**

| Parameter                                          | BER-AR, SBES                                                            | Reference                                                 |
|----------------------------------------------------|-------------------------------------------------------------------------|-----------------------------------------------------------|
| <b>Measure Description and Identification</b>      |                                                                         |                                                           |
| Measure                                            | ENERGY STAR® rated hot food holding cabinet, rebated after installation | -                                                         |
| Baseline                                           | Standard hot food holding cabinet                                       | -                                                         |
| <b>General Parameters</b>                          |                                                                         |                                                           |

| Interactive Effects Factor for Peak Demand Savings | 0                                                                       | See Subsection 5.11.1                                     |

### Electrical Unitary Energy Savings

The electrical unitary energy savings for hot food holding cabinets are calculated using the ENERGY STAR Commercial Kitchen Calculator using the parameters in Table 317 below.

**Table 317: Electrical Unitary Energy Savings Values for Hot Food Holding Cabinets**

| Parameter                                                                                                                                | Symbol | BER-AR R, SBES                                                 | Reference                                 |
|------------------------------------------------------------------------------------------------------------------------------------------|--------|----------------------------------------------------------------|-------------------------------------------|
| Annual Days of Operation [days/year]                                                                                                     | DAYS   | Actual                                                         | Measure specific - use information in TS  |
| Average Daily Operation [hours/day]                                                                                                      | HOU    | Actual                                                         | Measure specific - use information in TS  |
| Interior Volume [ft³]                                                                                                                    | -      | Actual                                                         | Measure specific - use information in TS  |
| The Rate of Energy Consumption While it Is Maintaining or Holding at the Control Setpoint Without Using a Humidity-generating Device [W] | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Energy Savings [kWh]                                                                                                                     | ES     | Calculated using the ENERGY STAR Commercial Kitchen Calculator | ENERGY STAR Commercial Kitchen Calculator |

## Unitary Peak Demand Savings

The unitary peak demand savings for hot food holding cabinets are calculated using the variables defined and listed in the equation and Table 318 below, as well as variables from Table 317 above.

$$\text{Peak Demand Savings}_{kW} = (ES \times PCF) / (HOU \times DAYS)$$

**Table 318: Unitary Peak Demand Savings Values for Hot Food Holding Cabinets**

| Parameter                       | Symbol                                  | BER-AR, SBES                                                  | Reference                |
|---------------------------------|-----------------------------------------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF                                     | Actual or 0.68                                                | As per Subsection 5.11.2 |
| Unitary Peak Demand Savings [W] | <i>Peak Demand Savings<sub>kW</sub></i> | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for hot food holding cabinets are assumed to be 100%.

## (6) Ice Machines

### Summary

Table 319 presents a summary of the values used to calculate electrical ice machines savings. The detailed methodology follows.

**Table 319: Ice Machine Measure Summary**

| Parameter                                          | BER-AR, SBES                                                  | Reference                                                 |

| The Type of Ice the Ice Maker Produces                                                                     | -      | Actual (Options: batch or continuous)                                                                                                         | Measure specific - use information in TS  |
| Harvest Rate - the Gross Weight of Ice Harvested in a 24-hour Period for Efficient Ice Maker [lbs ice/day] | -      | Actual or ENERGY STAR default                                                                                                                 | Measure specific - use information in TS  |
| The Measured Energy Use (or energy consumption rate) for the Efficient Ice Maker [kWh / 100 lbs]           | -      | Actual or ENERGY STAR default                                                                                                                 | Measure specific - use information in TS  |
| Energy Savings [kWh]                                                                                       | ES     | Calculated using the ENERGY STAR Commercial Kitchen Calculator                                                                                | ENERGY STAR Commercial Kitchen Calculator |

## Unitary Peak Demand Savings

The unitary peak demand savings for ice machines are calculated using the variables defined and listed in the equation and Table 321 below, as well as variables from Table 320 above.

$$Peak\ Demand\ Savings_{kW} = (ES \times PCF) / (HOU \times DAYS)$$

**Table 321: Unitary Peak Demand Savings Values for Ice Machines**

| Parameter                       | Symbol                       | BER-AR, SBES                                                  | Reference                |
|---------------------------------|------------------------------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF                          | Actual or 0.68                                                | As per Subsection 5.11.2 |
| Unitary Peak Demand Savings [W] | $Peak\ Demand\ Savings_{kW}$ | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for ice machines are assumed to be 100%.

## (7) Ovens

### Summary

Table 322 presents a summary of the values used to calculate electrical ovens savings. The detailed methodology follows.

**Table 322: Oven Measure Summary**

| Parameter                                          | BER-AR, SBES                                                  | Reference                                                 |

### Electrical Unitary Energy Savings

The electrical unitary energy savings for ovens are calculated using the ENERGY STAR Commercial Kitchen Calculator using the parameters in Table 323 below.

**Table 323: Electrical Unitary Energy Savings Values for Ovens**

| Parameter                                                                       | Symbol | BER-AR R, SBES                                                 | Reference                                 |
|---------------------------------------------------------------------------------|--------|----------------------------------------------------------------|-------------------------------------------|
| Annual Days of Operation [days/year]                                            | DAYS   | Actual                                                         | Measure specific - use information in TS  |
| Average Daily Operation [hours/day]                                             | HOU    | Actual                                                         | Measure specific - use information in TS  |
| Size                                                                            | -      | Actual (FULL size or HALF size)                                | Measure specific - use information in TS  |
| The Number of Pans a Combination Oven Can Accommodate                           | -      | Actual or ENERGY STAR default (N/A for convection ovens)       | Measure specific - use information in TS  |
| Food Cooked per Day [pounds]<br>Pro-rate Based on HRS (if HRS do not equal 12). | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Cooking Energy Efficiency of Efficient Oven (CEE)                               | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Production Capacity of Efficient Oven [lbs/hr]                                  | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Idle Energy Rate of Efficient Oven [Watts]                                      | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Energy Savings [kWh]                                                            | ES     | Calculated using the ENERGY STAR Commercial Kitchen Calculator | ENERGY STAR Commercial Kitchen Calculator |

## Unitary Peak Demand Savings

The unitary peak demand savings for ovens are calculated using the variables defined and listed in the equation and Table 324 below, as well as variables from Table 323 above.

$$Peak\ Demand\ Savings_{kW} = (ES \times PCF) / (HOU \times DAYS)$$

**Table 324: Unitary Peak Demand Savings Values for Ovens**

| Parameter                       | Symbol                       | BER-AR, SBES                                                  | Reference                |
|---------------------------------|------------------------------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF                          | Actual or 0.68                                                | As per Subsection 5.11.2 |
| Unitary Peak Demand Savings [W] | $Peak\ Demand\ Savings_{kW}$ | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for ovens are assumed to be 100%.

## (8) Steam Cookers

### Summary

Table 325 presents a summary of the values used to calculate electrical steam cooker savings. The detailed methodology follows.

**Table 325: Steam Cooker Measure Summary**

| Parameter                                          | BER-AR, SBES                                                  | Reference                                                 |

### Electrical Unitary Energy Savings

The electrical unitary energy savings for steam cookers are calculated using the ENERGY STAR Commercial Kitchen Calculator using the parameters in Table 326 below.

**Table 326: Electrical Unitary Savings Values for Steam Cookers**

| Parameter                                                                       | Symbol | BER-AR R, SBES                                                 | Reference                                 |
|---------------------------------------------------------------------------------|--------|----------------------------------------------------------------|-------------------------------------------|
| Annual Days of Operation [days/year]                                            | DAYS   | Actual                                                         | Measure specific - use information in TS  |
| Average Daily Operation [hours/day]                                             | HOU    | Actual                                                         | Measure specific - use information in TS  |
| Type of Steam                                                                   | -      | Actual (steam generator, boilerless, boiler based)             | Measure specific - use information in TS  |
| The Maximum Number of Full-sized Pans                                           | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Food Cooked per Day [pounds]<br>Pro-rate Based on HRS (if HRS do not equal 12). | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Cooking Energy Efficiency of Efficient Steam Cooker (CEE)                       | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Idle Energy Rate of Efficient Oven [Watts]                                      | -      | Actual or ENERGY STAR default                                  | Measure specific - use information in TS  |
| Energy Savings [kWh]                                                            | ES     | Calculated using the ENERGY STAR Commercial Kitchen Calculator | ENERGY STAR Commercial Kitchen Calculator |

## Unitary Peak Demand Savings

The unitary peak demand savings for steam cookers are calculated using the variables defined and listed in the equation and Table 327 below, as well as variables from Table 326 above.

$$Peak\ Demand\ Savings_{kW} = (ES \times PCF) / (HOU \times DAYS)$$

**Table 327: Unitary Peak Demand Savings Values for Steam Cookers**

| Parameter                       | Symbol                                  | BER-AR, SBES                                                  | Reference                |
|---------------------------------|-----------------------------------------|---------------------------------------------------------------|--------------------------|
| Peak Coincidence Factor         | PCF                                     | Actual or 0.68                                                | As per Subsection 5.11.2 |
| Unitary Peak Demand Savings [W] | <i>Peak Demand Savings<sub>kW</sub></i> | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for steam cookers are assumed to be 100%.

## 5.12 Commercial Laundry Equipment

### 5.12.1 Interactive Effects

Interactive effects are assumed to be nil for laundry measures since they usually exhaust heat through outdoor vents and drain water.

## 5.12.2 Peak Demand Savings Factor

For laundry measures, peak demand savings are determined by multiplying the wattage by a PCF value of 34%, which was established as part of the 2015 evaluation of BER.<sup>337</sup>

## 5.12.3 Adjustment Ratios

For laundry measures, no adjustment ratios were calculated.

## 5.12.4 Commercial Laundry Measures

### (9) Commercial Washing Machines

#### Summary

Table 328 presents a summary of the values used to calculate commercial washing machine savings. The detailed methodology follows.

**Table 328: Commercial Washing Machine Measure Summary**

| Parameter                                          | BER-AR, SBES                                                                                                                                            | Reference                                                 |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for commercial washing machine are calculated using the variables defined and listed in the equation and Table 329 below.

$$\Delta kWh = \left( \frac{1}{MEF_b} - \frac{1}{MEF_e} \right) \times CAP \times LOADS \times QTY$$

**Table 329: Electrical Unitary Energy Savings Values for Commercial Washing Machines**

## Unitary Peak Demand Savings

The unitary peak demand savings for commercial washing machine are calculated using the variables defined and listed in the equation and Table 330 below, as well as variables from Table 329 above.

$$\Delta kW = \left( \frac{1}{MEF_b} - \frac{1}{MEF_e} \right) \times CAP \times LOADS \times QTY \times RUNTIME \times \frac{1}{LOADS} \times PCF$$

**Table 330: Unitary Peak Demand Savings Values for Commercial Washing Machines**

| Parameter                       | Symbol      | BER-AR, SBES                                                  | Reference             |
|---------------------------------|-------------|---------------------------------------------------------------|-----------------------|
| Length of Average Cycle [h]     | RUNTIME     | Actual or 1                                                   | Use information in TS |

| Unitary Peak Demand Savings [W] | $\Delta kW$ | Calculation based on specification data for each rebated unit | Calculation           |

## Installation Rates

Installation rates for commercial washing machine are assumed to be 100%.

<sup>338</sup> According to E1's current version of the ENERGY STAR Commercial Clothes Washer Savings Calculator, the default number of loads for Multi-unit Residential is now 1,241.

## (10) Commercial Heat Pump Clothes Dryers

### Summary

Table 331 presents a summary of the values used to calculate commercial heat pump clothes dryers savings. The detailed methodology follows.

**Table 331: Commercial Heat Pump Clothes Dryer Measure Summary**

### Electrical Unitary Energy Savings

The electrical unitary energy savings for commercial heat pump clothes dryers are calculated using the variables defined and listed in the equation<sup>339</sup> and Table 332 below.

$$\Delta kWh = QTY \times C_{dry} \times Load_{avg} \times \left( \frac{1}{CEF_{base}} - \frac{1}{CEF_{ee}} \right)$$

<sup>339</sup> Efficiency Vermont, *Technical Reference User Manual Measure Savings Algorithms and Cost Assumptions*, March 2015.

## Unitary Peak Demand Savings

The unitary peak demand savings for commercial heat pump clothes dryers are calculated using the variables defined and listed in the equation and Table 333 below, as well as variables from Table 332 above.

$$\Delta kW = \frac{Load_{avg} \times \left( \frac{1}{CEF_{base}} - \frac{1}{CEF_{ee}} \right)}{time_{cycle}} \times PCF \times QTY$$

**Table 333: Unitary Peak Demand Savings Values for Commercial Heat Pump Clothes Dryers**

| Parameter                       | Symbol      | BER-AR, SBES                                                  | Reference             |

| Interactive Effects Factor for Peak Demand Savings | 0                                                                                                    | See Subsection 5.11.1                                     |

### Electrical Unitary Energy Savings

The electrical unitary energy savings for demand-controlled kitchen exhaust are calculated using the variables defined and listed in the equation and Table 335 below.

$$\text{Energy Savings}_{kWh} = \text{ESVG} \times \text{HP}$$

**Table 335: Electrical Unitary Energy Savings Values for Demand Controlled Kitchen Exhaust**

| Parameter                                           | Symbol                        | BER-AR R, SBES                                                   | Reference                            |

## Unitary Peak Demand Savings

The unitary peak demand savings for demand controlled kitchen exhaust are calculated using the variables defined and listed in the equation and Table 336 below, as well as variables from Table 335 above.

$$\text{Peak Demand Savings}_{kW} = \text{DSVG} \times \text{PCF} \times \text{HP}$$

**Table 336: Unitary Peak Demand Savings Values for Demand Controlled Kitchen Exhaust**

| Parameter                       | Symbol                     | BER-AR, SBES                                                  | Reference                |
|---------------------------------|----------------------------|---------------------------------------------------------------|--------------------------|
| Demand Savings Factor (kW/hp)   | DSVG                       | 0.76                                                          | Pennsylvania TRM 2016    |
| Peak Coincidence Factor         | PCF                        | 0.68                                                          | As per Subsection 5.11.2 |
| Unitary Peak Demand Savings [W] | <i>Peak Demand Savings</i> | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for demand-controlled kitchen exhaust are assumed to be 100%.

## 5.13 Commercial IT and Datacentres

### 5.13.1 Interactive Effects

Interactive effects factors are not included in commercial IT and datacentre measures.

### 5.13.2 Peak Demand Savings Factor

No standard PCF values have been determined for commercial IT and datacentre measures.

### 5.13.3 Adjustment Ratios

For IT and datacentres measures, no adjustment ratios were calculated.

## 5.13.4 Commercial IT and Datacentres

### (1) Server-based Power Management Software

#### Summary

Table 337 presents a summary of the values used to calculate server-based power management software savings. The detailed methodology follows.

**Table 337: Server-based Power Management Software Measure Summary**

#### Electrical Unitary Energy Savings

The electrical unitary energy savings for server-based power management software are calculated using the variables defined and listed in the equation<sup>342</sup> and Table 338 below.

$$\Delta kWh = ESF_D * Q_D + ESF_L * Q_L$$

<sup>342</sup> Pennsylvania PUC, *Technical Reference Manual (TRM) Volume 1*, August 2019.

**Table 338: Electrical Unitary Energy Savings Values for Server-based Power Management Software**

| Parameter                                    | Symbol       | BER-AR, SBES                                                  | Reference                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Unitary Peak Demand Savings

The unitary peak demand savings for server-based power management software are calculated using the variables defined and listed in the equation and Table 339 below, as well as variables from Table 338 above.

$$\Delta kW = DSF_D * Q_D + DSF_L * Q_L$$

<sup>343</sup> Retrieved from <https://www.energystar.gov/sites/default/files/asset/document/LowCarbonITSavingsCalc.xlsx>.

## Electrical Unitary Energy Savings

The electrical unitary energy savings for server virtualization and decommissioning are calculated using the variables defined and listed in the equation<sup>344</sup> and Table 341 below.

$$\Delta kWh = (kWh_{BV} - kWh_{AV}) / VH$$

$$kWh_{BV} = \frac{8,760}{1,000} \times RS \times (W_{rs, idle} + U_{rs} * (W_{rs, full load} - W_{rs, idle}))$$

$$kWh_{AV} = \frac{8,760}{1,000} \times VH \times (W_{vh, idle} + U_{vh} * (W_{vh, full load} - W_{vh, idle}))$$

**Table 341: Electrical Unitary Energy Savings Values for Server Virtualization and Decommissioning**

| Parameter                                            | Symbol        | BER-AR, SBES                                                  | Reference             |

| Hours of Use [h/year]           | HOU         | 8760                                                          | Assumption  |
| Unitary Peak Demand Savings [W] | $\Delta kW$ | Calculation based on specification data for each rebated unit | Calculation |

## Installation Rates

Installation rates for server virtualization and decommissioning are estimated at 100%.

## (3) Uninterruptible Power Supply (UPS)

### Summary

Table 343 presents a summary of the values used to calculate uninterruptible power supply (UPS) savings. The detailed methodology follows.

**Table 343: Uninterruptible Power Supply (UPS) Measure Summary**

| Parameter                                          | BER-AR, SBES                                                                   |                                                           | Reference |
|----------------------------------------------------|--------------------------------------------------------------------------------|-----------------------------------------------------------|-----------|
| Measure Description and Identification             |                                                                                |                                                           |           |
| Measure                                            | ENERGY STAR® certified UPS to reduce energy losses, rebated after installation | -                                                         |           |
| Baseline                                           | No UPS                                                                         | -                                                         |           |
| General Parameters                                 |                                                                                |                                                           |           |
| Installation Rate                                  | 100%                                                                           | See details below under Installation Rates                |           |
| Effective Useful Life [years]                      | 10                                                                             | See Subsection 6.2                                        |           |
| Electrical Savings Parameters                      |                                                                                |                                                           |           |
| Unitary Energy Savings [kWh/year]                  | Calculation based on specification data for each rebated unit                  | See details below under Electrical Unitary Energy Savings |           |
| Unitary Peak Demand Savings [W]                    | 0                                                                              | No peak demand reduction                                  |           |
| Interactive Effects Factor for Energy Savings      | 0                                                                              | See Subsection 5.13.1                                     |           |
| Interactive Effects Factor for Peak Demand Savings | 0                                                                              | See Subsection 5.13.1                                     |           |

## Electrical Unitary Energy Savings

The electrical unitary energy savings for uninterruptible power supply (UPS) are calculated using the variables defined and listed in the equation<sup>345</sup> and Table 344 below.

$$\Delta kWh = 204 \times kVA$$

<sup>345</sup> California Municipal Utilities Association, *Savings Estimation Technical Reference Manual*, 2017, p.8-15.

**Table 344: Electrical Unitary Energy Savings Values for Uninterruptible Power Supply (UPS)**

| Parameter                         | Symbol       | BER-AR, SBES                                                  | Reference                |
|-----------------------------------|--------------|---------------------------------------------------------------|--------------------------|
| Energy Use per Rated kVA          | -            | 204                                                           | CMUA California 2017 TRM |
| UPS Power [kVA]                   | $kVA$        | Actual                                                        | Use information in TS    |
| Unitary Energy Savings [kWh/year] | $\Delta kWh$ | Calculation based on specification data for each rebated unit | Calculation              |

## Installation Rates

Installation rates for uninterruptible power supply (UPS) are estimated at 100%.

## 6 Effective Useful Life

This section outlines the EUL values used to calculate lifetime energy savings. This section also presents EUL values for demand reduction measures; these values are not used to calculate lifetime energy savings since those measures do not save energy. For demand response measures, the EUL represents the number of years for which the demand reduction is expected to persist. The EUL values should be used when calculating cost-effectiveness ratios for measures, in order to account for lifetime benefits.

### 6.1 LED Lamps and Fixtures

To establish lifetime energy savings for LED lamps and fixtures, the equipment life is determined using rated lifetimes identified in product specification sheets and annual HOU, as described in the equation below.

$$\text{Equipment Life [Years]} = \frac{\text{Rated Lifetime [Hours]}}{\text{Annual HOU [Hours]}}$$

Since regulatory changes will cause the baseline to increase over the lifetime of LEDs and thus decrease annual savings over the lifetime of the product, an equivalent EUL is necessary to determine lifetime savings. The equivalent EUL is multiplied by first-year savings to obtain lifetime energy savings. Since the equivalent EUL is based on upcoming regulatory changes, it must be updated annually to take into account the changing duration of each baseline. The detailed assumptions and calculations to obtain equivalent EUL values are presented in Appendix III.

Table 345 summarizes the equivalent EUL values for BNI LED lamps and fixtures.

**Table 345: EUL Values for BNI LED Lamps and Fixtures**

| Measure                               | Program Component    | Average Rated Lifetime (hours) | Annual HOU (hours/year) | Equipment Life | 2024 Equivalent EUL |
|---------------------------------------|----------------------|--------------------------------|-------------------------|----------------|---------------------|
| <b>LED Linear Fixtures</b>            |                      |                                |                         |                |                     |
| 1 x 4 Luminaires                      | BER-IR, BER-AR, SBES | 50,000                         | 4,209                   | 11.9           | 11.9                |
| 2 x 2 Luminaires and Retrofit Kits    | BER-IR, BER-AR, SBES | 50,000                         | 4,209                   | 11.9           | 11.9                |
| 2 x 4 Luminaires and Retrofit Kits    | BER-IR, BER-AR, SBES | 50,000                         | 4,209                   | 11.9           | 11.9                |
| Linear Ambient and Low-bay Luminaires | BER-IR, BER-AR, SBES | 50,000                         | 4,209                   | 11.9           | 11.9                |
| High-bay Luminaires                   | BER-AR, SBES         | 100,000                        | 4,209                   | 23.8           | 23.8                |
| Troffers                              | BER-IR, BER-AR, SBES | 90,000                         | 4,209                   | 21.4           | 21.4                |

## 6.2 Other Measures

The EUL values for non-LED lighting measures were established by conducting a literature review of technical reference manuals (TRMs) and studies from other similar jurisdictions.

Table 346 summarizes the EUL values and their source for Business, non-profit, and institutional (BNI) measures.

**Table 346: EUL Values for Non-LED Lighting BNI Measures**

| Measure Name                                      | Program Component    | EUL Value | Reference                                                                                                                                                |
|---------------------------------------------------|----------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Lighting Controls</b>                          |                      |           |                                                                                                                                                          |
| Occupancy Sensors                                 | BER-IR, BER-AR, SBES | 10        | GDS, 2007 (Table 2 – Commercial & Industrial Measures, value for occupancy sensors in new constructions)                                                 |
| <b>Agriculture</b>                                |                      |           |                                                                                                                                                          |
| Agriculture Heat Pads                             | BER-AR, SBES         | 10        | IESO PMA List, 2019 (Value for single creep heat pads)                                                                                                   |
| Dairy Scroll Compressors                          | BER-AR, SBES         | 15        | IESO PMA List, 2019 (Value for milk scroll compressors)<br>KEMA, 2009 <sup>346</sup> (Value for scroll compressors for dairy refrigeration)              |
| Energy Efficient Ventilation and Circulation Fans | BER-AR, SBES         | 15        | GDS, 2007 (Appendix C)<br>KEMA, 2009 (Value for ventilation fans, high efficiency)                                                                       |
| Heat Reclaimer Units                              | BER-AR, SBES         | 15        | Pennsylvania TRM, 2016<br>KEMA, 2009 (Value for process heat recovery)                                                                                   |
| High-volume Low-speed Fans                        | BER-AR, SBES         | 15        | IESO PMA List, 2019 (Value for high-volume low-speed fans)<br>KEMA, 2009 (Value for high-volume low-speed fans)<br>DEER, 2008 (Value for two-speed fans) |
| Low-energy and Zero-energy Livestock Waterers     | BER-AR, SBES         | 10        | KEMA, 2009 (Value for energy efficient livestock waterers)<br>IESO PMA List, 2019 (Value for low-energy livestock waterers)                              |
| Milk Pre-coolers                                  | BER-AR, SBES         | 15        | KEMA, 2009 (Value for well water pre-coolers)                                                                                                            |
| Natural and Dual Ventilation                      | BER-AR, SBES         | 15        | IESO PMA List, 2019 (Value for dual and natural exhaust ventilation systems)                                                                             |
| Tractor Engine-block Heater Timers                | BER-AR, SBES         | 5         | Minnesota TRM, 2020 (Value for agriculture – engine block heater timers)<br>IESO PMA List, 2019 (Value for engine block heater timers)                   |
| VFD for Milk Vacuum Pumps                         | BER-AR, SBES         | 15        | KEMA, 2009 (Value for VFD on milk vacuum pumps)<br>DEER, 2008 (Value for milking vacuum pump variable speed drives)                                      |
| VFD for Milk Transfer Pumps                       | BER-AR, SBES         | 15        | DEER, 2014 (Value for milking transfer pump variable speed drives)                                                                                       |

<sup>346</sup> KEMA. Focus on Energy Evaluation Business Programs: Measure Life Study. Prepared for PA Consulting Group Inc., August 2009.

| Measure Name                                                           | Program Component | EUL Value | Reference                                                                                                                                                                                                                            |
|------------------------------------------------------------------------|-------------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Compressed Air</b>                                                  |                   |           |                                                                                                                                                                                                                                      |
| Air-entraining Air Nozzles                                             | BER-AR, SBES      | 15        | KEMA, 2009 (Value for compressed air nozzles)                                                                                                                                                                                        |
| Cycling Air Dryers                                                     | BER-AR, SBES      | 10        | KEMA, 2009 (Value for cycling air dryers)                                                                                                                                                                                            |
| No-loss Drains                                                         | BER-AR, SBES      | 15        | ERS, 2005 <sup>347</sup> (Table 1-2, value for compressed air)                                                                                                                                                                       |
| Compressed Air Leak Repairs                                            | Custom            | 2         | KEMA, 2009 <sup>348</sup> (Value for compressed air - service)                                                                                                                                                                       |

| <b>HVAC</b>                                                            |                   |           |                                                                                                                                                                                                                                      |
| Air-source Heat Pumps Greater Than or Equal to 65,000 Btu/hr           | BER-AR, SBES      | 20        | California Public Utilities Commission, 2024 <sup>349</sup> (Value for HVAC heat pump)                                                                                                                                               |
| Air-source Heat Pumps Less Than 65,000 Btu/hr (Excluding Air-to-water) | BER-AR, SBES      | 18        | GDS, 2007 (Table 1 – Residential Measures, value for AC/heat pump, assuming air-source heat pumps of smaller capacities, mostly mini-split systems, have operating conditions closer to residential)                                 |
| Air-to-water Heat Pumps                                                | BER-AR, SBES      | 15        | GDS, 2007 (Table 2 – Commercial & Industrial Measures, value for packaged AC/HP)<br>ERS, 2005 (Table 4-7, value for packaged AC/HP)                                                                                                  |
| Dual-enthalpy Economizer Controls                                      | BER-AR, SBES      | 10        | GDS, 2007 (Table 2 – Commercial & Industrial Measures, value for enthalpy economizers)<br>ERS, 2005 (value for enthalpy economizers)                                                                                                 |
| Ground-source Heat Pumps                                               | BER-AR, SBES      | 25        | Life expectancy estimated by the U.S. Department of Energy <sup>350</sup> (up to 24 years for the inside component and more than 50 years for the ground loop) and by Natural Resources Canada <sup>351</sup> (about 20 to 25 years) |
| HVAC Hotel Occupancy Sensors                                           | BER-AR, SBES      | 8         | DEER, 2014 (Value for occupancy sensors)                                                                                                                                                                                             |
| Packaged Terminal Heat Pumps (PTHPs)                                   | BER-AR, SBES      | 15        | GDS, 2007 (Table 2 – Commercial & Industrial Measures, value for packaged AC/HP)                                                                                                                                                     |
| Water-source Heat Pumps                                                | BER-AR, SBES      | 15        | GDS, 2007 (Table 2 – Commercial & Industrial Measures, value for packaged AC/HP)<br>ERS, 2005 (Value for WSHP)<br>DEER 2014 (Value for high-efficiency water-source heat pumps)                                                      |
| Electric Thermal Storage                                               | BER-AR, SBES      | 18        | The EUL is expected to be comparable to other heating systems. The EUL therefore corresponds to the value used for stoves, furnaces/boilers, and air-source heat pumps                                                               |
| Advanced RTU Controls                                                  | BER-AR            | 10        | Illinois TRM, 2021 (Value for advanced RTU controls)                                                                                                                                                                                 |
| Smart Thermostats for Electric Heating                                 | BER-AR, BER-IR    | 8         | Wisconsin TRM, 2024 (Value for Smart Thermostats for Business)                                                                                                                                                                       |

## APPENDIX I

# Verification of Climate Validity for Interactive Effects Calculations

The climate data of Nova Scotia and Quebec for the duration of the heating and cooling seasons were analyzed as part of the 2015 evaluation and found to be comparable, and thus the 1992 ADS study results are applicable for EfficiencyOne (E1) lighting measures. This appendix presents the analysis conducted in 2015.

### Verification of Climate Data Validity

Considering that the 1992 ADS study remains the only well-documented study for cold climates, it is still used to establish interactive effects. To ensure that the findings of the ADS study are valid and applicable to Nova Scotia, Nova Scotia's climate characteristics were compared with those of Quebec to determine whether it is appropriate to use the weather data used in the ADS study in the impact evaluation of Nova Scotia's programs.

This analysis was conducted based on the assumption that internal gains (from lighting, DHW or any other appliances) reduce the heating load as long as the outdoor temperature is below the balance temperature of the building (and the opposite during the cooling season). This would mean that the most significant variable involved in calculating the interactive effect factors is the duration of the heating and cooling seasons, rather than the total heating and cooling degree days in a given climate.

The following two figures show the average heating degree days (HDD) and cooling degree days (CDD) per day over a full year in Trois-Rivières<sup>359</sup> and Halifax, respectively.

**Figure 1: HDD per Day for Trois-Rivières and Halifax**

<sup>359</sup> Since this city is located about halfway between Montreal and Quebec City, it is representative of the climate used in the ADS study.

Figure 2: CDD per Day for Trois-Rivières and Halifax

In the case of HDD, Figure 1 shows that Trois-Rivières' heating season ends about 15 days earlier than Halifax (based on the assumption that heating is turned on when there are around 5 HDD per day). Indeed, the heating season ends around May 20 in Trois-Rivières and around June 4 in Halifax. In both cities, the heating season starts around the 270<sup>th</sup> day of the year, which roughly falls on September 28. As for the cooling season, Figure 2 indicates that it starts around the 160<sup>th</sup> day and the 180<sup>th</sup> day in Trois-Rivières and Halifax, respectively, and ends around the 250<sup>th</sup> day in both cities.

In conclusion, the heating season is about 6% shorter in Trois-Rivières than in Halifax, while the former cooling season is about 22% longer than the latter. This means that the interactive effect factors based on the ADS study slightly underestimate the negative interactive effects occurring during the heating season in Nova Scotia; however, the Evaluator considers this 6% difference not significant. The overestimation of the cooling season also results in a positive impact on the interactive effects; nevertheless, because of the very small impact of cooling on the interactive effects (3.6% according to the ADS study), the overestimation is considered negligible. Therefore, the Evaluator concludes that the findings of the ADS study are still applicable to Nova Scotia.

## APPENDIX II

### Detailed Calculations of 2024 Equivalent EUL Values for LED Lamps and Fixtures

This appendix presents how the equivalent effective useful life (EUL) of LED lamps and fixtures were calculated for applicable measures in the EPI and Instant Savings program components. An equivalent EUL corresponds to the number of years by which the first-year savings need to be multiplied to obtain the lifetime savings.

The Evaluator first calculated the equipment life of each type of lamp and fixture, as presented in Table 347. The equipment life was calculated as the ratio between the manufacturer rated lifetime for the lamps and fixtures installed under the program components and the annual HOU values used to calculate unitary savings values.

**Table 347: Equipment Life Value per LED Lamp and Fixture Types**

| LED Lamp and Fixture Type                              | Program Component | Average Rated Lifetime Hours (hours) <sup>360</sup> | Annual HOU (hours/year) <sup>361</sup> | Equipment Life (years) |
|--------------------------------------------------------|-------------------|-----------------------------------------------------|----------------------------------------|------------------------|
| LED A19 Lamps                                          | EPI               | 25,000                                              | 949                                    | 26                     |
| LED Reflector Lamps                                    |                   | 25,000                                              | 949                                    | 26                     |
| LED Decorative Lamps                                   |                   | 15,000                                              | 949                                    | 16                     |
| LED Non-A-type Lamps (R, BR, and Decorative)           | Instant Savings   | 15,952                                              | 1,022                                  | 16                     |
| LED Non-A-type Lamps (Excluding R, BR, and Decorative) |                   | 25,000                                              | 1,022                                  | 24                     |
| LED Recessed Downlight Fixtures                        |                   | 37,400                                              | 1,022                                  | 37                     |
| LED Fixtures Without Motion Sensors                    |                   | 50,000                                              | 1,022                                  | 49                     |
| LED Fixtures with Motion Sensors                       |                   | 49,044                                              | 1,059                                  | 46                     |

<sup>360</sup> Based on manufacturer specification sheets for the most popular models installed through EPI in 2017.

<sup>361</sup> Based on the unitary savings review.

## Rationale for Using an Equivalent EUL

The LED market is evolving rapidly, driven in part by government regulations. LED products installed today are likely to become the baseline before the end of their rated lifetime since LED technologies are developing quickly and prices are falling. Some jurisdictions have already applied a reduced equivalent EUL to their lighting savings by adopting a higher baseline to represent savings in future years. In other words, their baseline increases over the lifetime of the product, which in turns reduces the equivalent EUL applied to first-year savings to obtain lifetime energy savings. The baseline is informed by government regulations as well as LED market information.

In terms of government regulations, the U.S. Energy Independence, and Security Act (EISA) 2020 requiring a minimum efficiency level for CFLs, also known as the EISA backstop, continues to be a key consideration.<sup>362</sup> The previous administration decided to eliminate the EISA backstop on inefficient lighting products. However, six states passed their own state legislation to implement the efficient lighting standards on January 1, 2020, regardless of what happened nationally. As of April 2022, the Biden administration restored the lighting standards for the extended definition of general service lamps (including decorative and reflector lamps) to the 45 lm/W efficiency standard. The standard will apply as of July 2023. In Canada, lighting has been added to the list of considered products for Amendments 18 and 19, which are planned to be at the pre-publication stage in early 2024. This would be consistent with the usual delay of approximately two years between Canadian and U.S. regulations as a new standard could be expected to be enforced in 2025.

While the latest U.S. regulation is set to establish a minimum efficiency level corresponding to a high-efficiency CFL, recent studies<sup>363</sup> indicate that the U.S. market is rapidly moving away from CFL lamps toward LED lamps. Steady shipment volumes, high LED shipment shares, elevated free-ridership levels, retailers' impressions on market saturation, and the greater availability of LED technologies compared to non-LEDs are all factors leading the Evaluator to believe that the markets for both LED A-type as well as LED non-A-type lamps are close to maturity. Although the Canadian general service lamp minimum energy performance has not yet been updated, it is expected that it will result in a ban on halogen incandescent lamps once it is applied. The Evaluator then expects LED technology to become the standard, a standard that most of the market has already attained. For these reasons, the Evaluator expects the baseline for LED lamps rebated on purchase to change in 2025; hence, 2024 is the last year with savings before the LED baseline is applied. The assumed baseline changes for A-type and non-A-type lamps are outlined in Table 348 below.

| Baseline                                                      | Minimum Wattage Requirement | Years                      | Rationale                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------|-----------------------------|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>A-type</b>                                                 |                             |                            |                                                                                                                                                                                                                                                                                                                                                                   |
| Incandescent Baseline                                         | N/A                         | 2024<br>(1,000 hours)      | Since incandescent lamps may no longer be replaced by incandescent lamps, there is a first increase in the baseline upon burnout. Incandescent light lamps have a typical rated life expectancy of 1,000 to 2,000 hours. <sup>364</sup> The remaining useful life of replaced functional incandescent light lamps is assumed to be half the rated life expectancy |
| LED Equivalent Baseline – American Legislation <sup>365</sup> | 45 lumens/W                 | 2025 - end of product life | See rationale above                                                                                                                                                                                                                                                                                                                                               |
| <b>Reflector (R, BR) and Decorative Lamps</b>                 |                             |                            |                                                                                                                                                                                                                                                                                                                                                                   |
| Halogen Incandescent Baseline                                 | N/A                         | 2024                       | The current Canadian regulations allow halogen incandescent lamps for reflector lamps (R, BR) and decorative. Therefore, the first baseline corresponds to the baseline product, namely halogen incandescent lamps                                                                                                                                                |
| LED Equivalent Baseline – American Legislation <sup>366</sup> | 45 lumens/W                 | 2025 - end of product life | See rationale above                                                                                                                                                                                                                                                                                                                                               |
| <b>Reflector (GU, PAR, MR) Lamps</b>                          |                             |                            |                                                                                                                                                                                                                                                                                                                                                                   |
| Halogen Baseline                                              | N/A                         | 2024                       | The current Canadian regulations allow halogen incandescent lamps for reflector lamps (GU, PAR, MR). Therefore, the first baseline corresponds to the baseline product, namely halogen lamps                                                                                                                                                                      |
| LED Equivalent Baseline – American Legislation <sup>367</sup> | 45 lumens/W                 | 2025 - end of product life | See rationale above                                                                                                                                                                                                                                                                                                                                               |

Using the baseline evolution presented above, the following sections present the detailed calculations and resulting values for all LED lighting products.

For direct-install programs (EPI) from an impact perspective, if an incandescent is replaced, E1 would be able to claim one year of savings. Indeed, if through these programs a functional non-LED bulb is replaced, savings are achieved and persist until that bulb burns out – the standard assumption is that savings are achieved for one year. After that one-year period, the bulb would have to be replaced with bulbs available in store, which are assumed to be LED starting in 2025.

## EPI

### LED A-type Lamps

LED A-type lamps installed under EPI replace incandescent lamps. The calculation is based on 9 W lamps because they are the most common A-type lamps installed through EPI. The first baseline increase occurs one year following the anticipated burnout of incandescent lamps.<sup>368</sup> Importantly, given their rated life of 25,000 hours and corresponding equipment life of 26 years, the baseline is affected by the change in regulation occurring in 2025. Starting in 2025 and for the remaining lifetime of those lamps (25 years), the baseline will be LED equivalent lamps as discussed above. The following equation is used to establish the equivalent EUL presented in Table 349.

$$\text{Equivalent EUL} = \frac{\Delta W_{\text{Incandescent}} \times 1 \text{ Year} + \Delta W_{\text{LED}} \times 25 \text{ Years}}{\Delta W_{\text{Incandescent}}}$$

**Table 349: Equivalent EUL Calculation Summary for LED A19 Lamps**

| Replaced Lamp (W) | Typical Efficient Lamp (W) | Incandescent Baseline 1 Year (2024) |                   | LED Equivalent Baseline – American Legislation 25 Years (2025-2049) |                   | Equivalent EUL (years) |
|-------------------|----------------------------|-------------------------------------|-------------------|---------------------------------------------------------------------|-------------------|------------------------|

| 100               | 9                          | 100                                 | 91                | 9                                                                   | 0                 | 1.0                    |

### Reflector Lamps

For reflector lamps, only the second and third baselines apply. While reflector lamps are not impacted by current Canadian regulations, they will be affected by the requirements of upcoming regulations (Amendments 18 & 19). Starting in 2025, the baseline wattage is therefore increased to a LED since the minimum efficiency level of 45 lumens/watt bans halogen lamps and the market moves away from CFL lamps. Therefore, these lamps will no longer generate savings starting in 2025 and only generate savings for the year prior to the baseline increase, which results in an equivalent EUL of one year.

### Decorative Lamps

As for decorative lamps (G25 and chandelier lamps), the same approach as for reflector lamps is applied. While both types of lamps are not impacted by current Canadian regulations, they will be affected by the requirements of upcoming regulations (Amendments 18 & 19). Starting in 2025, the baseline wattage is therefore increased to a LED and will no longer generate savings. They only generate savings for the year prior to the baseline increase, which results in an equivalent EUL of one year.

For solar fixtures, a measure life of 10 years was assumed based on the EUL values for motion sensors. While solar lamps initially remove the full wattage of the baseline lamps from the grid, the baseline wattage is assumed to become LED lamps starting in 2025. Therefore, the wattage of outdoor fixtures with motion sensors was assumed starting in 2025 until the end of the measure life. An equivalent EUL was obtained using the equation and the value presented in Table 350 below, which corresponds to 2.5 years.

<sup>368</sup> Assuming the remaining lifetime is 1,000 hours for incandescent lamps and that they are used 2.6 hours per day, they will burnout in approximately one year.

$$\text{Equivalent EUL} = (\Delta W_{\text{Initial}} \times 1 \text{ Year} + \Delta W_{\text{LED}} \times 9 \text{ Years}) / \Delta W_{\text{Initial}}$$

**Table 350: Equivalent EUL Calculation for Solar Fixtures**

| Average Replaced Lamp (W) | Average Wattage of Efficient Lamp (W) | Halogen Incandescent Baseline – Canadian Legislation<br>1 Year (2024) |                   | LED Equivalent Baseline – American Legislation <sup>369</sup><br>9 Years (2025-2033) |                   |

## Instant Savings

### LED Non-A-type Lamps

For LED non-A-type lamps sold through Instant Savings, lifetime energy savings values were established for the different types of lamps replaced, which mostly included reflector (R, BR, GU, PAR, MR) and decorative lamps. Reflector and decorative lamps are not impacted by the current Canadian regulation, although they are impacted by EISA 2020. Therefore, starting in 2025, the baseline wattage is increased to match that of LED technology since the minimum efficiency level of 45 lumens/watt bans halogen lamps and the market moves away from CFL lamps. Therefore, these lamps will no longer generate savings starting in 2025 and only generate savings for the year prior to the baseline increase, which results in an equivalent EUL of one year.

### LED Fixtures

As for LED fixtures without motion sensors (including recessed downlight fixtures), the equivalent EUL is analyzed in the same manner as for replace-on-burn-out lamps since the energy consumption of these fixtures is the consumption of the lamps provided with them. Therefore, the baseline is a fixture with lamps meeting current energy efficiency standards. Moreover, those lamps will be affected by the requirements of upcoming regulations (Amendments 18 & 19). Hence, starting in 2025, the baseline wattage is increased to a LED since the minimum efficiency level of 45 lumens/watt bans halogen lamps and the market moves away from CFL lamps. Therefore, like non-A-type lamps, LED fixtures will no longer generate savings starting in 2025 and only generate savings for the year prior to the baseline increase, which results in an equivalent EUL of one year.

For LED fixtures with motion sensors, the lifetime energy savings are calculated by first considering the reduced wattage and then the reduction in hours of use due to the motion sensor. The baseline for LED fixtures with motion sensors is reflector lamps for the majority (89%) of units sold. Therefore, based on the average daily HOU of 4.69, the same methodology as for LED non-A-type lamps is applied, as presented in Table 351.

<sup>369</sup> As imposed by U.S. federal legislation. Incandescent Equivalent 2nd Tier EISA 2007.

**Table 351: Lifetime Energy Savings for LED Fixtures with Motion Sensors – Reduced wattage**

| Average Replaced Lamp (W) | Average Wattage of Efficient Lamp (W) | Halogen Incandescent Baseline – Canadian Legislation 1 Year (2024) |                   | LED Equivalent Baseline – American Legislation <sup>370</sup> 23 Years (2025-2047) |                   | Lifetime Energy Savings (kWh) |
|---------------------------|---------------------------------------|--------------------------------------------------------------------|-------------------|------------------------------------------------------------------------------------|-------------------|-------------------------------|
|                           |                                       | Baseline Wattage                                                   | Displaced Wattage | Baseline Wattage                                                                   | Displaced Wattage |                               |
| 131                       | 22.4                                  | 131                                                                | 109               | 22.4                                                                               | 0                 | 187                           |

Then, the difference in hours of operation generated by the motion sensors was considered, as presented in Table 352.

**Table 352: Lifetime Energy Savings for LED Fixtures with Motion Sensors – Reduced Hours of Use**

| Old Average Hours of Use (hours per day) | New Average Hours of Use (hours per day) | Average Wattage of Efficient Lamp | Measure Life (years) | Lifetime Energy Savings (kWh) |
|------------------------------------------|------------------------------------------|-----------------------------------|----------------------|-------------------------------|
| 4.69                                     | 2.90                                     | 22.4                              | 10.0                 | 146                           |

The total lifetime energy savings of 333 kWh were divided by the first-year savings of 202 kWh to obtain an equivalent EUL of 1.6 years.

For solar fixtures, a measure life of 10 years was assumed based on the EUL values for motion sensors. While solar lamps initially remove the full wattage of the baseline lamps from the grid, the baseline wattage is assumed to become LED lamps starting in 2025. Therefore, the wattage of the outdoor fixtures with motion sensors was assumed starting in 2025 until the end of the measure life. An equivalent EUL was obtained using the equation and Table 353 below, which corresponds to 1.9 years.

$$\text{Equivalent EUL} = (\Delta W_{\text{Initial}} \times 1 \text{ Year} + \Delta W_{\text{LED}} \times 9 \text{ Years}) / \Delta W_{\text{Initial}}$$

**Table 353: Equivalent EUL Calculation for Solar Fixtures**

## APPENDIX III

### Detailed Calculations of 2024 Equivalent EUL Values for LED Lamps and Fixtures

This appendix presents how the equivalent effective useful life (EUL) of LED lamps and fixtures were calculated for applicable measures in the SBES program component. An equivalent EUL corresponds to the number of years by which the first-year savings need to be multiplied to obtain the lifetime savings.

The Evaluator first calculated the equipment life of each type of lamp and fixture, as presented in Table 354. The equipment life was calculated as the ratio between the manufacturer rated lifetime for the lamps and fixtures installed under the program components and the annual HOU values used to calculate unitary savings values.

**Table 354: Equipment Life Value per LED Lamp and Fixture Types**

| LED Lamp and Fixture Type            | Program Component | Average Rated Lifetime Hours (hours) <sup>372</sup> | Annual HOU (hours/year) <sup>373</sup> | Equipment Life (years) |
|--------------------------------------|-------------------|-----------------------------------------------------|----------------------------------------|------------------------|
| LED General-use and Decorative Lamps | SBES              | 25,000                                              | 3,600                                  | 6.9                    |
| Reflector Lamps                      |                   | 25,000                                              | 3,600                                  | 6.9                    |
| Non-recessed Downlight Fixtures      |                   | 50,000                                              | 3,600                                  | 13.9                   |
| Recessed Downlight Fixtures          |                   | 50,000                                              | 3,600                                  | 13.9                   |

<sup>372</sup> Based on manufacturer specification sheets for the most popular models installed through EPI in 2017.

<sup>373</sup> Based on the unitary savings review.

## Rationale for Using an Equivalent EUL

The LED market is evolving rapidly, driven in part by government regulations. LED products installed today are likely to become the baseline before the end of their rated lifetime since LED technologies are developing quickly and prices are falling. Some jurisdictions have already applied a reduced equivalent EUL to their lighting savings by adopting a higher baseline to represent savings in future years. In other words, their baseline increases over the lifetime of the product, which in turns reduces the equivalent EUL applied to first-year savings to obtain lifetime energy savings. The baseline is informed by government regulations as well as LED market information.

In terms of government regulations, the U.S. Energy Independence and Security Act (EISA) 2020 requiring a minimum efficiency level for CFLs, also known as the EISA backstop, continues to be a key consideration.<sup>374</sup> The previous administration decided to eliminate the EISA backstop on inefficient lighting products. However, six states passed their own state legislation to implement the efficient lighting standards on January 1, 2020, regardless of what happened nationally. As of April 2022, the Biden administration restored the lighting standards for the extended definition of general service lamps (including decorative and reflector lamps) to the 45 lm/W efficiency standard. The standard will apply as of July 2023. In Canada, lighting has been added to the list of considered products for Amendments 18 and 19, which are planned to be at the pre-publication stage in early 2024. This would be consistent with the usual delay of approximately two years between Canadian and U.S. regulations as a new standard could be expected to be enforced in 2025.

While the latest U.S. regulation is set to establish a minimum efficiency level corresponding to a high-efficiency CFL, recent studies<sup>375</sup> indicate that the U.S. market is rapidly moving away from CFL lamps toward LED lamps. Steady shipment volumes, high LED shipment shares, elevated free-ridership levels, retailers' impressions on market saturation, and the greater availability of LED technologies compared to non-LEDs are all factors leading the Evaluator to believe that the markets for both LED A-type as well as LED non-A-type lamps are close to maturity. Although the Canadian general service lamp minimum energy performance has not yet been updated, it is expected that it will result in a ban on halogen incandescent lamps once it is applied. The Evaluator then expects LED technology to become the standard, a standard that most of the market has already attained. For these reasons, the Evaluator expects the baseline for LED lamps to change in 2025; hence, 2024 is the last year with savings before the LED baseline is applied. The assumed baseline changes for A-type and non-A-type lamps are outlined in Table 355 below.

## SBES

### LED General-use and Decorative Lamps

The methodology used to establish the equivalent EUL of general-use and decorative lamps is based on the information presented in Table 356 and the equation below. The equivalent EUL calculation is based on 9 W LED lamps. The baseline technology is assumed to be a mix of 60 W incandescent lamps and 43 W halogen incandescent lamps, which yields an average baseline of 52 W.

Since incandescent lamps can no longer be replaced by incandescent lamps, there is a baseline increase upon burnout. These lamps are assumed to have a remaining lifetime of 1,000 hours, which translates to 0.28 years with an annual HOU of 3,600 hours. Since SBES targets commercial participants, it is assumed that some participants might have incandescent lamps stocked and, therefore, the Evaluator increased the duration of this baseline to a full year.

As outlined in Table 355 above, the equipment life of this product is 6.9 years, meaning the corresponding baseline will be affected by the change in legislation occurring in 2025. Starting in 2025 and for the remaining lifetime of the fixture (5.9 years), the baseline will be a LED, which results in no additional savings. With the information presented in Table 356, the following equation served to set the equivalent EUL of general-use and decorative lamps at 1.0 year.

$$\text{Equivalent EUL} = \frac{\Delta W_{\text{Halogen Incandescent and Incandescent}} \times 1 \text{ Year} + \Delta W_{\text{LED}} \times 5.9 \text{ Years}}{\Delta W_{\text{Halogen Incandescent and Incandescent}}}$$

**Table 356: Baseline Evolution During the Effective Useful Life of LED General-use and Decorative Lamps**

| Typical Replaced Lamp (W) | Typical Efficient Lamp (W) | Incandescent and Incandescent Baseline 1 Year (2024) |                   | LED Equivalent Baseline – American Legislation <sup>380</sup> 5.9 Years (2025-2030) |                   | Equivalent EUL (years) |
|---------------------------|----------------------------|------------------------------------------------------|-------------------|-------------------------------------------------------------------------------------|-------------------|------------------------|
|                           |                            | Baseline Wattage                                     | Displaced Wattage | Baseline Wattage                                                                    | Displaced Wattage |                        |
| 52                        | 9                          | 52                                                   | 43                | 9                                                                                   | 0                 | 1.0                    |

### Reflector Lamps

LED reflector lamps typically replace halogen lamps. As outlined in Table 347 further above, their average rated life is estimated at 25,000 hours, which translates into an equipment life of 6.9 years. With the regulation planned to impact reflector lamps in 2025, the baseline wattage will be reduced to a LED starting in 2025 and for the remaining lifetime of the fixture (4.9 years). The equivalent EUL was calculated at 1.0 year based on the following equation and the information presented in Table 357.

$$\text{Equivalent EUL} = \frac{\Delta W_{\text{Halogen}} \times 1 \text{ Year} + \Delta W_{\text{LED}} \times 5.9 \text{ Years}}{\Delta W_{\text{Halogen}}}$$

<sup>380</sup> As imposed by U.S. federal legislation. Incandescent Equivalent 2<sup>nd</sup> Tier EISA 2007.

| 43                        | 12                         | 43                                | 31                | 12                                                                                        | 0                 | 1.0                       |

### Non-recessed LED Downlight Fixtures

Since non-recessed LED downlight fixtures replace fixtures using A-type lamps, the methodology for establishing their equivalent EUL is similar to that of A-type lamps in Efficient Product Installation (EPI). The equivalent EUL calculation is based on the typical case of 9 W LED lamps and the first baseline increase occurs one year following the anticipated burnout of incandescent lamps. Importantly, given their rated life of 50,000 hours and corresponding equipment life of 13.9 years, the baseline is affected by the change in regulation occurring in 2025. Starting in 2025 and for the remaining lifetime of the fixture (12.9 years), the baseline will be a LED, which results in no additional savings. The equation and Table 358 below present the information used to calculate the equivalent EUL of 1.0 years.

$$Equivalent\ EUL = \frac{\Delta W_{Halogen\ Incandescent\ and\ Incandescent} \times 1\ Year + \Delta W_{LED} \times 12.9\ Years}{\Delta W_{Halogen\ Incandescent\ and\ Incandescent}}$$

**Table 358: Baseline Evolution During the Effective Useful Life of Downlight Fixtures**

| Typical Replaced Lamp (W) | Typical Efficient Lamp (W) | Halogen Incandescent and Incandescent Baseline<br>1 Year (2024) |                   | LED Equivalent Baseline -<br>American Legislation <sup>382</sup><br>12.9 Years (2025-2037) |                   | Equivalent EUL<br>(years) |
|---------------------------|----------------------------|-----------------------------------------------------------------|-------------------|--------------------------------------------------------------------------------------------|-------------------|---------------------------|
|                           |                            | Baseline Wattage                                                | Displaced Wattage | Baseline Wattage                                                                           | Displaced Wattage |                           |
| 52                        | 9                          | 52                                                              | 43                | 9                                                                                          | 0                 | 1.0                       |

### Recessed Downlight Fixtures

Since LED recessed downlight fixtures replace fixtures typically housing reflector lamps for which the baseline technology is halogen lamps, the methodology for establishing their equivalent EUL is similar to that of reflector lamps. The EUL of LED recessed downlight fixtures is established at 13.9 years based on a rated life of 50,000 hours. The equivalent EUL calculation is based on the typical case of a 12 W LED reflector lamp replacing a 43 W halogen lamp. With the regulation planned to impact reflector lamps in 2025, LED lamps will become the baseline for the remaining lifetime of LED recessed downlight fixtures (12.9 years). The equivalent EUL was calculated at 1.0 year based on the information presented in Table 359.

$$Equivalent\ EUL = \frac{\Delta W_{Halogen} \times 1\ Year + \Delta W_{LED} \times 12.9\ Years}{\Delta W_{Halogen}}$$

## APPENDIX IV

### Interactive Effects Methodology for Commercial Lighting

The interactive effects calculation methodology for commercial lighting was revised as part of the 2024-2025 DSM Measure Assessment update. This appendix details how the calculations were performed to obtain revised interactive effect factors, which will be applied to the 2025 savings only, since the new approach requires certain changes in the tracking data and to adjustment ratios.

### Calculation Approach

Pursuant to a literature review of methodologies used by other jurisdictions and of the Uniform Methods Project recommendations, the Evaluator decided to continue applying an engineering calculation approach to estimate interactive effects factors while making some updates to reflect the latest knowledge and available data. The engineering calculations are based on the following general equations for energy interactive effects and for peak demand savings interactive effects.

$$IE_E\% = \%LightingIndoor \times \%LightingHeatConditioned \times (BuildingHeatE + BuildingCoolE)$$

$$BuildingHeatE = f_{heat} \div HeatCOP = \frac{-HoursLightingHeat}{HoursLighting} \div HeatCOP$$

$$BuildingCoolE = f_{cool} \div CoolCOP = \frac{HoursLightingCool}{HoursLighting} \div CoolCOP$$

Where:

- › *%LightingIndoor*: The percentage of fixtures and lamps that are installed in indoor conditioned spaces as only those result in interactive effects.
- › *%LightingHeatConditioned*: The percentage of heat generated by lighting and that is produced inside the conditioned space for indoor lighting. This considers the fact that some fixtures generate a portion of their heat in ceiling plenums or in high ceilings where that heat does not impact the space heating or cooling load.
- › *BuildingHeatE*: The energy interactive effects factor associated with the facility and heating system type.
- › *BuildingCoolE*: The energy interactive effects factor associated with the facility and cooling system type.
- › *f<sub>heat</sub>*: The fraction of lighting hours during which the heat generated impacts on the heating load.
- › *f<sub>cool</sub>*: The fraction of lighting hours during which the heat generated impacts on the cooling load.
- › *HoursLightingHeat*: The number of annual hours when both lights and the heating system are on.
- › *HoursLighting*: The number of annual hours when the lights are on.
- › *HeatCOP*: The efficiency of the heating system.
- › *HoursLightingCool*: The number of annual hours when both lights and the cooling system are on.
- › *CoolCOP*: The efficiency of the cooling system.

The equation for peak demand savings interactive effects follows the same general principles with the difference that the *HoursHeatingPeak* and *HoursPeak* only consider hours that coincide with the peak demand period defined as non-holiday weekdays between 5 p.m. and 7 p.m. in December, January, and February. These variables do not include whether lights are on or not because, if lights are off during these peak hours, the peak demand savings are nil (i.e. the value of the interactive effects factors do not matter). Cooling system operation is not considered for peak demand savings as cooling systems are assumed to not operate during winter peak conditions. The peak demand savings interactive effects factors are therefore calculated as:

$$IE_{PD}\% = \%LightingIndoor \times \%LightingHeatConditioned \times BuildingHeatPD \\ = \%LightingIndoor \times \%LightingHeatConditioned \times \left( \frac{-HoursHeatPeak}{HoursPeak} \div HeatCOP \right)$$

Where:

- › *HoursHeatPeak*: The number of annual hours of the peak demand period when the heating system is on.
- › *HoursPeak*: The number of annual hours of the peak demand period.
- › *BuildingHeatPD*: The peak demand interactive effects factor associated with the facility and heating system type.

The savings with interactive effects (either electrical energy or peak demand) should then be calculated as follows.

$$Savings\ with\ IE = Savings \times (1 + IE_E\%)$$

The following subsections first describe how the building-specific and system-specific intermediate values are obtained (*BuildingHeatE*, *BuildingCoolE*, and *BuildingHeatPD*) and then detail the estimates of *%LightingIndoor* and *%LightingHeatConditioned* variables. The last subsection explains how the values are applied to commercial lighting measures in various program components.

## Calculation of Building and System-Specific Intermediate Values

This first subsection details how the *BuildingHeatE*, *BuildingCoolE*, and *BuildingHeatPD* variables are calculated.

### Lighting Operation Schedule

Each building archetype (as tracked in the BER-AR and SBES tracking sheets) is assigned a typical lighting operation schedule as per Table 360.

**Table 360: Lighting Operation Schedule per Building Archetype**

| Building Archetype              | 8 A.M to 4 P.M. | 8 A.M. to 6 P.M. | 24 hours |
|---------------------------------|-----------------|------------------|----------|
| Agriculture                     | X               |                  |          |
| Banking / Financial             | X               |                  |          |
| Education                       | X               |                  |          |
| Entertainment / Public Assembly | X               |                  |          |
| Healthcare                      |                 |                  | X        |
| Hospitality                     |                 |                  | X        |
| Manufacturing / Industrial      |                 | X                |          |
| Office / Commercial             | X               |                  |          |
| Public Service                  | X               |                  |          |
| Residential                     |                 |                  | X        |
| Restaurant / Bar                |                 | X                |          |
| Retail                          |                 | X                |          |
| Technology / Science            | X               |                  |          |
| Warehouse / Storage             |                 |                  | X        |

It is approximated that lighting is on during these hours for all seven days of the week. Interactive effects factors are calculated for these hours specifically.

## Operation of Building Heating and Cooling Systems

To identify hours during which heating and cooling systems are on, outdoor temperatures as well as the building balance temperatures are considered.

### Balance Temperature

The heating balance temperature is the outdoor temperature below which a heating system will operate to meet thermal comfort requirements in a building. The cooling balance temperature is the outdoor temperature above which a cooling system will operate to meet thermal comfort requirements in a building. While it is difficult to obtain a reference balance temperature for commercial buildings in the literature (since the balance temperature is specific to each building), values in the range of 55°F (or 13°C) to 65°F (18°C) are often mentioned in resources for modellers and, in the Evaluator's experience, are common in hourly measurement and verification energy regressions for commercial buildings. The Uniform Methods Project does not make specific recommendations for the balance temperature of commercial buildings, but it notes that, for residential buildings, 60°F (15.5°C) and 70°F (21°C) are typical balance temperatures for heating and cooling respectively.<sup>384</sup> These values are expected to be higher than those for commercial buildings. The New York interactive effects calculation file<sup>385</sup> assumes a heating balance temperature of 50°F (10°C) and a cooling balance temperature of 60°F (15.5°C). In light of this information, the Evaluator used a balance temperature of 13°C for heating and 18°C for cooling.

## Weather Data

To determine whether each hour of the year is below the heating balance temperature or above the cooling balance temperature, a typical meteorological year based on a 15-year average (2008 to 2023) was built.

## Heating and Cooling Season

Temperatures below 13°C might occur during parts of the year when heating systems are not active, in which case efficient lighting would have no impact on the heating load. The same concept is true of temperatures above 15°C for cooling systems. Therefore, the Evaluator established a heating season and a cooling season to delimitate the periods during which lighting might impact heating and cooling loads. The heating season was estimated to be between October 1 and April 30 as there are fewer than five degree-days per day outside of these dates.<sup>386</sup> The remainder of the year was considered to be the cooling season.

## Heating and Cooling System Efficiency

For each measure installed in BER-AR or SBES, the space heating and cooling systems are known and the efficiency of each is applied as per the following table.

| Table 361: Coefficient of Performance (COP) by Space Heating and Cooling Systems Heating and Cooling System | COP | Reference                                                                               |
|-------------------------------------------------------------------------------------------------------------|-----|-----------------------------------------------------------------------------------------|
| Electric resistance heating                                                                                 | 1.0 | Convention                                                                              |
| Heat pump heating                                                                                           | 1.8 | COP of a standard mini-split heat pump based on an HSPF2 Region V of 6.0 <sup>387</sup> |
| Air conditioning                                                                                            | 2.5 | Assumption <sup>388</sup>                                                               |

## Building and System-specific Intermediate Value Results

Using the equations and the parameters described above, the Evaluator developed the *BuildingHeatE* and *BuildingCoolE* tables below for electrical energy consumption and peak demand. The information in the tables is applicable to both SBES and BER-AR. For lighting measures installed under these program components, interactive effects factors should be selected based on the facility type in which measures are installed as well as the type of electrical heating and cooling systems serving the space.

<sup>386</sup> This assumption was also used in the analysis of the residential interactive effects as presented in appendix of the 20224-2025 DSM Residential Measure Assessment.

<sup>387</sup> Assuming an average HSPF2 of 6.0 for Region V, which corresponds to the minimum for “split system central heat pumps, other than those that are small-duct and high-velocity or space-constrained” as per the NRCan regulation available at <https://natural-resources.canada.ca/energy-efficiency/energy-efficiency-regulations/guide-canadas-energy-efficiency-regulations/split-system-central-air-conditioners-and-heat-pumps/6895>.

<sup>388</sup> This assumption was not documented in the initial methodology. It is consistent with the assumption made in the reference study used for residential interactive effects ADS ASSOCIÉS, Évaluations des effets énergétiques combinés des mesures d'économies d'énergie – résidence unifamiliale, report presented to Hydro-Québec, 1992.

**Table 362: *BuildingHeatE* and *BuildingCoolE* by Facility Type and Heating and Cooling System Type**

| Facility Type                   | BuildingHeatE                         |                                          |                      | BuildingCoolE       |

## Estimate of Percentage of Heat Generated in Indoor Conditioned Spaces

This subsection presents the estimates of the *%LightingIndoor* and *%LightingHeatConditioned* variables.

The *%LightingIndoor* variable indicates whether a specific measure is installed indoor (100%) or outdoor (0% as measures installed outdoor do not generate interactive effects). This information comes from each specific measure in the tracking sheet.

The *%LightingHeatConditioned* variable represents the percentage of heat generated by lighting and that is produced inside the conditioned space for indoor lighting. This considers the fact that some fixtures generate a portion of their heat in ceiling plenums or in high ceilings where that heat does not impact the space heating or cooling load. This variable is specific to the measure types installed as outlined in Table 364.

**Table 364: Values for %LightingHeatConditioned per Measure Type**

| Measure Type                               |              | % Heat in Conditioned Space |
|--------------------------------------------|--------------|-----------------------------|
| Linear LED Fixtures                        | Recessed     | 57% <sup>389</sup>          |
|                                            | Non-recessed | 100%                        |
| Linear LED Lamps                           | Recessed     | 57%                         |
|                                            | Non-recessed | 100%                        |
| High Bay Fixtures                          |              | 0% <sup>390</sup>           |
| Outdoor LED Fixtures                       |              | 0%                          |
| Directional and Architectural LED Fixtures |              | 100%                        |
| Indoor Occupancy/Motion Sensors            |              | 100%                        |
| Outdoor Motion Sensors                     |              | 0%                          |
| LED Lamps (SBES – CDI only)                |              | 100%                        |
| LED Nightlights (SBES – CDI only)          |              | 100%                        |

## Application of IE Tables

For BER-AR and SBES, the calculation methodology should be applied for each measure using project-specific information tracked in the CIS starting in early 2025. The table below lists the fields required.

**Table 365: Tracking Sheet Fields Required for Interactive Effect Calculations**

| Field               | Used for Variables                                 | Available in SBES?                                                                                                                                                                                                                        | Available in BER-AR?                                                                                                           |
|---------------------|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| Indoor/Outdoor      | %LightingIndoor                                    | Not specifically. Indicated in Measure Location, but not in a standardized field. In the absence of this information, assumptions can be made by measure category since measures tend to be installed almost all indoors or all outdoors. |                                                                                                                                |
| Facility Type       | BuildingHeatE,<br>BuildingCoolE,<br>BuildingHeatPD | Yes                                                                                                                                                                                                                                       | Yes, but is indicated as “IE/IEpd Override” in a large proportion of cases – the facility type should be recorded in all cases |
| Heating System Type | BuildingHeatE,<br>BuildingHeatPD                   | Yes                                                                                                                                                                                                                                       | Yes, but does not differentiate between electric resistance and heat pump                                                      |
| Cooling System Type | BuildingCoolE                                      | Yes                                                                                                                                                                                                                                       | Yes                                                                                                                            |
| Measure Type        | %LightingHeatConditioned                           | Yes                                                                                                                                                                                                                                       | Yes                                                                                                                            |

E1 will be adding tracking fields in BER-AR over the course of 2025 to ensure that all required information (as noted in Table 365) is available to implement the new interactive effect calculations. The Evaluator will also work with E1 to classify a comprehensive list of measure types as recessed or non-recessed. This information will be collected in 2025 through a review of new data that are expected to become available in the DLC Qualified Products List<sup>391</sup> and possibly through the site visits that will be conducted as part of the 2025 DSM evaluation for BER-AR. The 2025 interactive effects factors for SBES and BER-AR, based on this new methodology, will then be used to estimate the average interactive effects for BER-IR.

<sup>389</sup> The estimation of the percentage of heat generated in the conditioned space is derived from Chantrasrisalai, C., and D.E. Fisher, “Lighting heat gain parameters: Experimental results.” in *HVAC&R Research* 13(2):305-324, 2007.

<sup>390</sup> The Evaluator assumes that the heat generated by high bay fixtures (that are installed in areas with high ceilings) remains largely at heights where the temperature is not controlled and therefore generates no significant interactive effects.

<sup>391</sup> If this is not available as expected, the Evaluator will conduct research on a sample of popular products.

## APPENDIX V

### Net-to-Gross Ratio Review

---

#### EXECUTIVE SUMMARY

EfficiencyOne (E1) commissioned Econoler to evaluate E1's 2023-2025 DSM program portfolio. As part of the evaluation scope, E1 asked Econoler to present a review of net-to-gross ratio (NTGR) best practices and update the free-ridership and participant spillover questionnaires and algorithms used in E1's DSM programs. The aim of this update is to ensure that the questionnaires and algorithms used are consistent across programs and in line with the latest best practices.

The findings presented herein are drawn from a combination of several references and Econoler's expertise and knowledge. The majority of the findings are based on the Uniform Methods Project (UMP) and the results of a review of publicly available questionnaires and algorithms contained in evaluation protocols, technical reference manuals (TRMs), and results reporting. Information was reviewed from Massachusetts, the IESO and Enbridge in Ontario, Rhode Island, Maine, and New Jersey.

The review focused solely on the self-report method, the most commonly used approach to estimate net savings and the current method employed in the E1 DSM evaluation. An approach to non-participant spillover or market effects was not included.

Based on Econoler's review of NTGR best practices using the self-report approach, Econoler has identified several aspects of the current approach that should be maintained and other areas that should be consistently updated across the portfolio moving forward.

#### Aspects Maintained

- › The overall adjustment approach to **cross-influence** currently used in E1 algorithms. This approach captures influences outside the program (e.g. past participation, educational initiatives, etc.), the results of which are then applied to total free-ridership score results.
- › The current method of capturing **spillover** with a focus on like spillover. Unlike spillover should be considered when a program is designed to influence participants to take further actions beyond what is included in the program (e.g. the educational aspect of the Efficient Product Installation program).
- › **Consistency checks.** Questions that serve to check for contradictions, compare responses to similar questions, and remove inconsistencies from the NTGR calculation continue to be important. Open-ended questions can be included for programs involving larger projects to provide context and a further consistency check.
- › **Number of questions.** The current questionnaire design (number of questions and framing) can be maintained, although language efficiencies may be employed where appropriate (see Key Changes below).

## Key Changes

- › **Averaging the intention and influence scores** to calculate free-ridership. This updated approach adopted by several jurisdictions ensures that both variables carry an equal weighting as decision-making factors. Econoler recommends that E1 move to this new approach.
- › Using a **four-point unbalanced scale for free-ridership and spillover**. Answer scales in E1 algorithms primarily use a 10-point numbered scale approach whereby only the first and last points of the scale are labelled. Econoler recommends moving to a four-point ordinal scale whereby all points are distinctly labelled for improved survey participant comprehension. The proposed scale is unbalanced since each scale point must be scored incrementally for the free-ridership algorithm.
- › **Simplifying question wording where possible**. Simple questions where possible help ensure clarity and comprehension for survey respondents. Econoler will continue to pre-test questionnaire changes among small respondent samples to ensure that questions are correctly understood before fully launching any survey.
- › Ensuring that the NTGR is considered for all measures, either utilizing a **deemed ratio or program-level ratio when not measured**. This would be the case for multi-measure programs (e.g. Efficient Product Installation) where it is not possible to collect data on all measures.

## INTRODUCTION

---

EfficiencyOne (E1), an independent, non-profit organization, is responsible for helping Nova Scotians improve the energy efficiency of their homes and workplaces by designing, marketing, and delivering demand-side management (DSM) for Nova Scotians. E1 provides energy efficiency, demand response, and carbon mitigation services through the Efficiency Nova Scotia (ENS) franchise. Regulatory oversight is provided by the Nova Scotia Utility and Review Board (NSUARB). E1 receives funding for its electrical DSM activities from Nova Scotia Power (NS Power) ratepayers.

E1 has a DSM portfolio of three residential programs and three business, non-profit, and institutional (BNI) programs that are marketed to Nova Scotians through the ENS franchise. Each program has one or more program components. Econoler was commissioned by E1 to evaluate E1's 2023-2025 DSM program portfolio.

This report presents a review of net-to-gross ratio (NTGR) best practices and updates the free-ridership and participant spillover questionnaires and algorithms used in E1's DSM programs so that they are consistent across programs and in line with the latest best practices.

The findings included in this report are drawn from a combination of several references and Econoler's expertise and knowledge. The majority of the findings included in this report are based on the Uniform Methods Project (UMP), and a review of publicly available questionnaires and algorithms contained in evaluation protocols, technical reference manuals (TRMs), and results reporting. Information was reviewed from Massachusetts, the IESO and Enbridge in Ontario, Rhode Island, Maine, and New Jersey.

The review is focussed only on the self-report method, the most commonly used approach to estimate net savings and the current method employed in evaluation. The review includes:

- › A summary of the latest best practices in NTGR algorithm development and survey design, based on a literature review.
- › A review and documentation of the Evaluator's overall approach and detailed rules for NTGR questionnaires and algorithms and how these align with best practices. The set of rules covers topics such as NTGR calculations, algorithm design, triangulation, correct formulation of survey questions, etc.
- › An update to NTGR algorithms used for E1's portfolio of DSM programs to ensure they continue to be aligned with best practices, account for all necessary factors and, where appropriate, use a consistent approach. Please note that this review does not provide an approach to non-participant spillover or market effects.

This document will be used to guide the NTGR data collection and analysis for the programs for which a NTGR update is planned in 2024 (i.e. Efficient Product Installation, Business Energy Rebates-Instant Rebates, and Custom; Instant Savings is excluded because data collection occurs too early in the year) and will be applied to other programs minimally for the remainder of the current DSM Plan period (i.e. 2023-2025) and in principle as long as a self-reporting NTGR approach is used.

This report is divided into several parts: the first concerns best practices and recommendations with respect to NTGR methodology and algorithm design, including study design and sampling; the second is focused on best practices and recommendations with respect to the self-report method, including survey and question design as well as data collection and triangulation. Next, a review of E1's current approach is provided with a summary of recommendations on what elements of the NTGR methodology should be maintained or updated based on this review. Finally, using these recommendations, the algorithms for EPI and BER-IR are reviewed and updated to reflect the recommendations as examples.

## 7 Net-to-gross Ratio (NTGR) Methodology

This section documents best practices and recommendations with respect to NTGR calculations, NTGR methodology, algorithm design, free-ridership (FR) and participant spillover (SO) scoring, consistency checking, as well as study design and sampling.

### 7.1 NTGR Algorithm

#### 7.1.1 The Net-to-gross Ratio Calculation

The NTGR is applied to a program to ensure the savings being attributed to the given program would not have happened naturally without the intervention of the program. It is best practice across all jurisdictions reviewed to include questions to capture, at minimum, free-ridership and spillover levels within a program evaluation scope and embed questions related to free-ridership and spillover within a self-reporting feedback questionnaire or interview guide. The formula associated with calculating a NTGR score is shown below.

$$\text{NTGR} = 1 - \text{Free-ridership} + \text{Spillover}$$

(energy savings that would have occurred without the program)      (additional non-incented savings attributable to the program)

#### Free-ridership Score Components

In calculating free-ridership, the self-report method is aimed at establishing how the participant decided to implement the energy efficient or demand response measure(s).

Three factors need to be considered:

- › Intention: The likelihood the participant would have implemented the measure without the program.
- › Influence: How the program impacted the participant's decision-making.
- › Cross-influence: How past efforts on the part of the program administrator influence the participant's intention and/or their decision-making.

Each factor is comprised of several elements to establish the most robust understanding of a participant's decision-making and program influence. Figure 3 below depicts the elements that are accounted for in each factor.

**Figure 3: Components of Free-ridership Score<sup>392</sup>**

**Intention** is scored using responses to a series of questions on several decision factors. Questionnaires typically begin with a simple question to assess whether a participant would have taken action without the program being in market (planning). Whether a participant would have paid for the measure(s) or procured/installed them on their own is also captured at this point in the questionnaire and used to calculate the first step of the intention score (cost, participant effort). To achieve further accuracy in the free-ridership score, another series of questions is asked to understand in more detail what the participant would have done without the program, capturing whether they would have postponed their project (timing), installed fewer or less efficient measures (quantity, efficiency). Responses on timing, quantity, and efficiency are used only to reduce, not increase the intention score. This approach, which was observed across the jurisdictions reviewed, ensures that responses indicating free-ridership are not double counted (e.g. a participant who intended to install a measure without the program (planning) will also likely respond accordingly to questions on quantity or efficiency).

The number and framing of questions to capture intention vary and should be tailored to the program and/or sector. For example, timing questions are generally irrelevant for end-of-life equipment replacement, and the quantity factor is not relevant when there is only one piece of equipment to be replaced (e.g. a water heater for a single-family home). For New Construction programs, the series of intention questions must be adjusted and tailored to the context of new construction projects such as the longer time horizon, impact of the building code in force and the different phases of the project (design, construction etc.).

**Influence** is measured as a single score taking the maximum score of an array of statements relating to program specific influence factors in one matrix-style question. This score accounts for the influence of program incentives, education, and resources provided by the program and advice and information received from program partners only.

<sup>392</sup> To see examples of actual questions used for the Intention and Influence components, please refer to Table 368 and Table 374 in Section 9.

The Evaluator came across two different approaches to account for **cross-influence**. The first approach includes past program participation and general energy efficiency awareness and education provided by the program administrator into the influence score. Therefore, cross-influence is looked at together with program influence factors to form one influence score. In the second approach, a **cross-influence score** is calculated by capturing influences outside the program such as past participation in another program, the program administrator's general education around energy efficiency, etc., and the results are then applied to the total free-ridership score as a further positive effect.<sup>393</sup> This approach considers that cross-influence can impact a participant's intention as well as influence. Only applying cross-influence to the influence score (as in the first approach) would decrease the weight of cross-influence on the scoring. E1 currently uses the second approach in establishing NTGRs, and the Evaluator recommends that this approach be maintained.

Figure 4 below illustrates the recommended **formula for calculating free-ridership**. Averaging the intention and influence scores ensures that intention and influence are weighted as equal decision-making factors, and this was observed in a number of jurisdictions that had recently reviewed and updated their NTGR approaches.<sup>394</sup> This differs from the approach currently applied by E1 where the various components of the participant's intention score are averaged with the influence score, thereby conferring a higher weight to the participant's intention as compared to the program's influence. The Evaluator recommends employing the above approach moving forward to ensure both factors are weighted equally in the free-ridership algorithms. As discussed above, the Evaluator recommends that cross-influence be applied as an overall adjustment.

**Figure 4: Free-ridership Equation**

$$\text{Free-ridership} = \left( \frac{\text{Intention} + \text{Influence}}{2} \right) \times \text{Cross-influence}$$

## Partial Free-riders

Free-ridership scores can vary between 0% and 100%. It is best practice to ensure free-ridership questions are nuanced to enable accounting for partial free-ridership. Partial free-riders are those who fall somewhere in between a full free-rider (100%) and instances where no free-ridership is present (0%). Measuring a series of factors (planning, cost, effort, timing, quantity, efficiency, influence, and cross-influence) allows for the free-ridership score to be adjusted to include partial free-riders.

### 100% score (free-rider):

- › Would have installed in the same timeframe and context
- › Would have installed the same quantity of measures and efficiency level
- › Installed measures prior to learning about program

### Partial free-rider:

- › Program had impact on quantity/timing/efficiency of upgrades, but not full impact
- › Aspects of the program influenced their decision to participate

### 0% score:

- › Would not have taken any action without the program

<sup>393</sup> Massachusetts and Rhode Island calculate a cross-influence score and apply the result to the overall free-ridership score.

<sup>394</sup> Massachusetts in 2022, New Jersey (new to DSM) in 2023, and Efficiency Maine's most recent C&I evaluation in 2023.

## Free-ridership Scoring

In the self-report method, an important consideration is scoring responses that are used to establish the free-ridership result. The scoring of individual scale points may vary based on the algorithm, but it is **best practice to ensure consistency in the number of scale points utilized and the labels associated with each point**. E1's current approach primarily uses a 10-point scale. While there is less consensus among practitioners in scales and scoring, a reduced scale (i.e. three, four or five point) is often used.

Econoler recommends moving to a four-point labelled scale format as outlined in Table 366 below. The four-point scale allows for each scale point to be labelled to enable the Evaluator to define what each scale point means, resulting in more uniform and accurate results. Further, Econoler recommends using an unbalanced scale for free-ridership related questions as each scale point must be scored incrementally and included in an algorithm. Note that the four-point scale is a guideline and may not be applicable to all questions (e.g. questions providing scenarios as the response) depending on the algorithm and program. The scoring presented in Table 366 provides an example and may be adjusted in algorithm development depending on the question and program.

**Table 366: Examples of Four-point Scales and Scoring**

| Scale Point | Influence              | Importance           | Likelihood           | Score                                       |
|-------------|------------------------|----------------------|----------------------|---------------------------------------------|
| 1           | Very influential       | Very important       | Definitely would     | 100%                                        |
| 2           | Somewhat influential   | Somewhat important   | Probably would       | 75%                                         |
| 3           | Not very influential   | Not very important   | Probably would not   | 25%                                         |
| 4           | Not at all influential | Not at all important | Definitely would not | 0%                                          |
| 98          | Don't know             |                      |                      | Remove or adapt if "Don't know" has meaning |
| 99          | Refused/Not applicable |                      |                      |                                             |

## Checking for Consistency

Ensuring consistency in responses is considered best practice according to the UMP and all jurisdictions studied; this is accomplished by including a series of questions to capture any responses that contradict other responses and/or by comparing responses to those of similar questions. E1's current approach includes checking for consistency, which should be maintained. The Evaluator recommends that three types of consistency checks be considered in free-ridership algorithms:

- 1) Including a follow-up question when an inconsistent response is given (i.e. "Just to confirm, ....").
- 2) Comparing responses (e.g. comparing the response to cost intention and cost influence and excluding responses if there is a significant difference between the two questions).
- 3) For BNI customers with larger projects, including open-ended questions to provide contextual information about participant's decision-making process (e.g. "Can you explain why your organization decided to build a better-than-code building?", "You explained that, without an incentive from E1, you would have designed a less efficient building. Can you explain how your building would have been different?").

## Spillover Score Components

Spillover is a component of the NTGR aimed at capturing further positive effects and is generally added to a questionnaire after free-ridership questions. The spillover series of questions is aimed at capturing other energy efficiency-related actions the participant took outside of the program and due to the influence of the program. If participant spillover is found to be attributable to a program, this improves the NTGR.

Table 367 provides the UMP definitions for like and unlike participant spillover.

**Table 367: Participant Spillover Types**

|                  |                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Like Spillover   | Program-induced actions taken outside of the program that are similar to the actions taken as part of the program. (i.e. if a participant in a program that offers rebates on a menu of measures seeks out incentives for some of the measures and after participation purchases/installs further measures incentivized through the program without applying for an incentive.) |
| Unlike Spillover | Program-induced actions taken outside of the program that are NOT similar to the actions taken as part of the program. (i.e. if a program participant installs further energy efficient measures not incentivized by the program but installs those further measures due to the influence of the program.)                                                                      |

Like and Unlike spillover is possible both at the site of the project incented by the program or at another site. Like spillover is most often captured in NTGR studies across the jurisdictions reviewed. Several jurisdictions noted that unlike spillover is difficult to capture via self-report surveys (see Rhode Island, 2021, pages 3, 12-13, 30-31, 53-54)<sup>395</sup>. Asking about further measures installed based on the existing measure list within a program is less complicated to capture in a survey format. Unlike spillover is more often studied when a program is designed to influence participants to take further actions beyond what is included in the program, i.e. when an educational component is part of program design. When a program is not designed to influence unlike spillover, unlike spillover will likely represent low to nil savings and be difficult to capture. The UMP notes that there is always a trade-off between cost and precision and the effort involved in capturing positive effects. The decision to study unlike spillover in a program should be weighed against the possible positive effects that can be reasonably captured. See Table 369 further below for the current approach to capturing spillover in E1's portfolio.

Econoler recommends continuing with the practice of formulating questions to capture like spillover and to consider adding questions to capture unlike spillover where the program is designed to encourage unlike spillover, such as when customer education is a major program component. When site visits are part of planned evaluation activities, these can be good opportunities to collect responses on spillover (e.g. for BNI programs).

Moreover, spillover is typically measured with participants after they have completed their participation in the program, but there are programs where participation may be cancelled or not completed. In these situations, these so-called partial participants may also be targeted for spillover measurement.

<sup>395</sup> See References Section, page 31 for full study information.

## Spillover Scoring

Typically, spillover is captured in a series of three to five questions to discern if any further energy efficiency-related actions took place after the participant took part in the program. If the participant took further energy efficiency actions outside of the program and without incentives, then the level of influence of the program on the participant's decision to take further actions is assessed. The savings<sup>396</sup> associated with the further actions taken AFTER participating are multiplied by the spillover score to obtain total spillover savings. The final spillover level is calculated by dividing the sum of spillover savings by program savings for all respondents.

**Figure 5: Spillover Estimation Equation**

Information to enable the calculation of savings for installed measures must be collected, and a follow-up telephone interview with technical staff to estimate savings should be planned for more complex measures or for measures that generate significant savings.

## 7.2 NTGR Study Design and Sampling

The following considerations are important when designing a study to capture the NTGR for any program.

- › Free-ridership should be explicitly considered for all measures in a program. Where possible, evaluation should serve to ensure every measure has a chance of being sampled to estimate a robust program-level NTGR. In specific cases, it may be necessary to exclude certain measures from the research, but another NTGR approach (see box below) should be used for these measures to establish a NTGR value. If multiple NTGRs are applied within one program, the values should be weighted according to the proportion of savings each measure or measure category contributes to the program. In these cases, if there is a measure-level NTGR calculated, where possible NTGR can be tracked at the measure level.

### Options for Combination Methods in Multi-measure Programs

If there are many measures in a program and the decision is made to include only the measures/measure categories with the highest proportion of savings in the NTGR survey questionnaire, the following approaches can be considered for the remaining measures:

- › Assign a deemed NTGR based on historic values or research in other jurisdictions (or both);
- › Use the NTGR calculated from other measures in the program.

<sup>396</sup> Average savings values are typically used for prescriptive and semi-prescriptive measures and for custom measures; technical questions are asked to quantify savings as accurately as possible.

- › The sample size should be designed to aim for a 90% confidence level and a 10% margin of error when based on the available population of projects in a program. Project-level sampling is best practice as survey questions are posed on a per project basis. However, this may not always be possible in programs with lower participation levels. In cases where a very small population is being studied, a census sampling approach may be appropriate.<sup>397</sup>
- › The target audience should be determined based on the program type and logic. If external stakeholders (e.g. governments, community organisations) or market actors (e.g. distributors, contractors) are involved in the promotion or delivery of the program and influence participants' decision-making around energy efficiency upgrades, their influence should be captured in the study. While feedback collected from program partners or other stakeholders can be simply utilized to confirm results received from participant feedback but not included in the NTGR scoring, Econoler recommends that program partner influence in the NTGR scoring be applied in program scoring as per the guidelines below:
  - › For midstream programs that are designed to augment energy efficiency product stocking and promotional practices, program partner/market actor scores should be included in the NTGR at the overall program level. E1 currently has one program, BER Instant Rebates (IR), that has some characteristics of a midstream program but is not strictly a midstream program as it is marketed by E1 to customers (e.g. contractors or business owners) and the incentive is passed directly to the participant (vs. the distributors retaining part of the incentive for stocking, processing, and promoting the products). Econoler recommends that the approach for BER-IR consider both the participant (end-users and contractors) and distributor perspectives, and that the distributor's influence be used to adjust the free-ridership if the participant was influenced by the distributor and if the distributor changed some of their practices due to the program.
  - › For downstream programs where the end user is the direct participant and recipient of the incentives, two approaches can be considered. The simplest option is to factor into the influence score the participant's perspective on the influence of the program partner's input or recommendations. For programs where the contractor's recommendation<sup>398</sup> is the primary mechanism for participation decision-making and the program is designed to influence channel/program partners, a more complex approach can be used to collect program partner feedback on the program's influence on their recommendations. In these cases, Econoler recommends that program partner responses be used to adjust the planning score of participants who said that they would have implemented the channel/program partner's recommendations in the absence of the program.
  - › The questionnaire should include a series of screening questions that will be utilized to determine if the contacts invited to take part in the study are the key decision-makers for the project/taking part in the DSM program (keep in mind that larger or more complex organizations may have multiple key decision-makers from various internal departments). Where multiple decision-makers are involved, an average of their answers is used.
  - › The frequency of conducting NTGR studies among other jurisdictions varies from every six months to every three years. Some jurisdictions conduct standalone NTGR studies (Massachusetts, gas programs in ON), although the most common practice is to measure NTGR as part of the regular evaluation cycle. The program evaluation timelines can also vary with the typical evaluation framework being three years and each program in a portfolio having a comprehensive evaluation, and thus updating the NTGR, at least once in the three-year cycle as is the case for E1's current framework. E1's Overall Strategic Evaluation Plan outlines its evaluation cycle and rationale.

<sup>397</sup> A census approach entails contacting all participants or channel partners in a program to respond to a survey with all efforts made to achieve a census; however a 100% response rate is not often achieved.

<sup>398</sup> Contractor influence should be validated through both participant surveys and contractor surveys ensuring that the recommendations that contractors are sharing have been influenced by the program.

## 7.3 Best Practices in Survey Design and Data Collection

Although various methods<sup>399</sup> can be used to calculate NTGRs,<sup>400</sup> the self-report survey approach is standard practice due to its overall cost-effectiveness, transparency, and flexibility. To estimate the free-ridership and spillover used in the NTGR calculation, survey questions are generally asked to target program participants, but can be also asked to other audiences, including partial participants, and market actors (e.g. energy managers, distributors, etc.) who may have influenced decision-making process. As explained later in this subsection, various data-collection modes can be used (telephone surveys, web surveys, or a mixture of both).

The elements listed below constitute an overview of the best practices for NTGR surveys, question design, and data collection.<sup>401,402,403,404,405</sup>

### Survey Design Elements

- › Identify the **key decision-maker** and interview others that **could have influenced the decision-making process** (e.g. energy managers, distributors)
- › Use **warm-up questions** to help respondents best recall their decision-making process (for standalone NTGR questionnaires)
- › As discussed above, use **consistency checks** to identify and address responses that contradict earlier answers
- › Use **measure-specific questions** to identify different motivations for installing different measures
- › Keep the survey **as short as possible** to avoid respondent fatigue (ideally no longer than 20 minutes)

### Question Design

- › Use simple words and avoid technical terms and slang
- › Use specific, clear wording rather than general, abstract terms
- › Use words that can be interpreted in only one way to avoid ambiguity
- › Use question wording that aligns with the audience's interpretation
- › Avoid questions with negatives (single or double)
- › Avoid positive (agree) and negative (disagree) responses in question wording (neutral language)
- › Avoid leading questions (meaning questions that direct to a certain answer) or loaded questions (meaning questions that assume something about the respondent) (e.g. You had already made the decision to purchase a heat pump before you learned about X program, correct?)
- › Ask one question at a time; avoid multiple variables in one question
- › (e.g. The program is simple and worthwhile)

<sup>399</sup> Other methods could include experimental design methods (such as randomized control trials), billing analysis, sales and/or market data analysis, expert-based opinion methods (like Delphi panels) or deemed/stipulated ratios applied to program savings.

<sup>400</sup> Alternative methods for evaluating NTGR include billing regression, discrete choice modeling.

<sup>403</sup> Violette, D.; Rathbun P. (2017). "Estimating Net Savings – Common Practices" Chapter 21 of *The Uniform Methods Project: Methods for Determining Energy Efficiency Savings for Specific Measures*.

<sup>404</sup> Baumgartner, R. (2013). "Survey Design and Implementation Cross-Cutting Protocols for Estimating Gross Savings" Chapter 12 of *The Uniform Methods Project: Methods for Determining Energy Efficiency Savings for Specific Measures*.

<sup>405</sup> Krosnick, J.A.; Presser, S. (2009). "Question and Questionnaire Design." Wright, J.D.; Marsden, P.V. eds. *Handbook of Survey Research* (2nd Edition). Elsevier: San Diego.

- › Use specific details to reduce recall errors and help set the scene (e.g. participation date, measures/upgrades received, incentive level, support received)
- › Provide **mutually exclusive and exhaustive response** categories
- › Ensure the order of response categories is **randomized** where it makes sense to do so to reduce respondent tendency to select answers earlier (web) or later (telephone) in a list.
- › Use **rating scales** (rather than ranking, which is more difficult for respondents to analyze)
- › Use **consistent scales**
  - › To improve data quality; questions with a lesser number of scale points are said to work best
  - › For numbered scales, labelling each scale point with words ensures consistency among responses
- › Use combinations of open and closed-ended questions for best results, particularly for projects with smaller samples. (Note that closed-ended questions are used more often, being easier to code, process, and analyze. With large sample sizes, a large number of open-ended questions is more time consuming and costly to conduct.)

## Question Order

- › Make **early questions easy and pleasant** to answer (to help settle the respondent)
- › Make **early questions** explicitly about the **survey topic**
- › For customers with larger projects, start the survey with an open-ended question to **uncover the narrative** about how the project came about and the rationale for the choice of energy efficient equipment
- › **Group together** questions on the same topic
- › Move **from more general to specific** questions on the same topic
- › Place **sensitive questions** at the end of the questionnaire
- › Use **filters** to avoid asking questions that are not applicable

## Data Collection Elements

- › **Pretest the survey** to ensure that:
  - › Questions are correctly understood
  - › Questions provide results that are valid and reliable
  - › Skips work as they should
  - › Questions and sections flow well
- › To improve response rates, **send out survey notifications** with utility/program administrator letterheads/logos; do multiple follow-ups; consider the use of incentives
- › Conduct the fieldwork **as soon as possible** after a measure has been installed to minimize recall bias.<sup>406</sup> (Note, however, that this may underestimate spillover since little time may have passed since the installation. A second survey could be conducted later if spillover is likely to have occurred and if budget allows. Spillover results can be higher after a certain time has passed to allow participants to complete further energy efficiency actions. However, recall can be negatively impacted overall, which can lead not only to less accurate FR results, but also less detailed general feedback on the program, such as awareness, motivations, barriers, etc.)
- › Use interviewers who have the necessary expertise

<sup>406</sup> Some jurisdictions use very short, fast feedback surveys (e.g. Energy Trust of Oregon, however, they only report gross savings).

**Table 368: Overview of NTGR Survey and Question Design Best Practices**

|  Survey Design |  Question Design |  Question Order |  Data Collection |
|-------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| › Identify key decision-maker                                                                   | › Use simple words                                                                                | › Make early questions easy and pleasant                                                         | › Pre-test the survey                                                                               |
| › Use warm-up questions                                                                         | › Ensure specific meaning, not abstract                                                           | › Make early questions survey topic specific                                                     | › Send out notifications and follow-ups                                                             |
| › Conduct consistency checks                                                                    | › Use words that have one clear interpretation to avoid ambiguity                                 | › For larger projects, start with an open-ended question to get a “story”                        | › Conduct fieldwork as soon as possible after installation                                          |
| › Use measure-specific questions                                                                | › Use question wording that aligns with the audience                                              | › Group together questions on same topic                                                         | › Use interviewers with the necessary expertise                                                     |
| › Ensure ideal duration                                                                         | › Avoid negatives (in question wording)                                                           | › Move from general to specific questions                                                        | › Remove missing, inconsistent, or uncertain responses from the data set prior to analysis          |
|                                                                                                 | › Avoid agree/disagree answers (in question wording)                                              | › Position sensitive questions at the end                                                        |                                                                                                     |
|                                                                                                 | › Avoid leading and loaded questions                                                              | › Use filters to avoid “not applicable” answers                                                  |                                                                                                     |
|                                                                                                 | › Avoid multiple variables in a question                                                          |                                                                                                  |                                                                                                     |
|                                                                                                 | › Use specific details to reduce recall errors                                                    |                                                                                                  |                                                                                                     |
|                                                                                                 | › Foster mutually exclusive, exhaustive responses                                                 |                                                                                                  |                                                                                                     |
|                                                                                                 | › Randomize responses                                                                             |                                                                                                  |                                                                                                     |
|                                                                                                 | › Use rating scales                                                                               |                                                                                                  |                                                                                                     |
|                                                                                                 | › Use consistent scales with a lesser number of scale points                                      |                                                                                                  |                                                                                                     |
|                                                                                                 | › Use combinations of open-ended and closed-ended questions                                       |                                                                                                  |                                                                                                     |

## Data-Collection Modes

**Telephone surveys** are relatively low cost, and fielding can be completed relatively quickly (compared to face-to-face interviews) but they may yield low response rates and should be limited in duration when no incentive is given (as is usually the case for NTGR evaluations). While computer-assisted telephone interviewing (CATI)<sup>407</sup> surveys can be administered for large sample sizes, it is standard practice to use non-CATI interviewing for smaller samples where the survey has more open-ended or probing questions.

<sup>407</sup> CATI survey questions and answer options are pre-programmed so that the interviewer reads exactly what they see on screen and selects the appropriate response. Non-CATI surveys allow a more subject-knowledgeable interviewer to probe open-ended questions in more depth to obtain fuller responses and to clarify any issues the respondent may have in understanding a question.

**Web surveys** are usually lower cost than telephone surveys (as there is no human component) and, once programmed, can be completed even more quickly. It is possible to obtain very large sample sizes in a short timeframe and respondents may be more willing to answer sensitive questions. That said, web surveys may not be suitable for certain populations (e.g. older people or those who are not comfortable using or do not have access to internet technology), and questions must be relatively simple to avoid misinterpretation.

**Intercept interviews** whereby an interviewer administers a survey to a consumer who has just purchased a certain product as they come out of the store is a useful, although expensive and time-consuming data-collection technique, particularly for instant rebate products or in programs for which the administrator collects no customer (participant) or product information.

While **mail-in paper questionnaires** are still used on occasion in some jurisdictions, response rates are much lower than for telephone surveys. Moreover, respondents can read ahead to see upcoming questions (which could alter their responses), and questions may be misinterpreted or missed altogether. This approach is becoming increasingly less common. That said, mail-in questionnaires can be helpful in targeting very difficult-to-reach population segments or as part of a mixed-mode approach.

Using **multiple or mixed-mode data-collection methods** has become standard practice in recent years to help reach different population targets and to overcome low response rates and coverage issues. Examples of mixed mode data collection include recruiting for the survey one way (e.g. via email) and collecting the data in another way (e.g. via phone), using different methods to target different study segments (e.g. participants via web and distributors via telephone), or even using different modes for completing separate survey sections (part telephone interview, part web exercise). Results from the various data-collection techniques are then triangulated for completeness and validation. There are no set rules on when to use a specific data-collection mode or in what combination. As mentioned above, it is standard practice to use web or telephone surveys to reach larger sample sizes when there are more closed-ended questions (e.g. for participants) and telephone interviews for smaller sample sizes when there are more open-ended questions (e.g. for distributors). The key element is to collect robust information to feed into the algorithm.

## Incentives

Incentives may be considered when it is necessary to maximize very small sample sizes, when response rates are very low, or to compensate for a lengthy interview duration (e.g. 45 minutes or longer). The amount and type of incentive depends on the sample being targeted.

## Triangulation

As mentioned earlier, triangulation consists of combining one or more data-collection methods. If applied correctly, the combination of methods enables a higher level of precision to be achieved but leads to an increase in time, budget, complexity and, in some cases, a heavier workload for respondents.

Triangulation can be conducted using only self-report approaches – for example, by interviewing program participants as well as market actors – allowing more robust results to be obtained and different respondent group results to be compared.

## 8 Analysis of E1's NTGR Approach

This section provides an overview of E1's current NTGR approach particularly as it relates to measures included in the NTGR calculation and spillover. An overview is presented on how the NTGR approach should be updated (or not) based on a review of best practices.

### 8.1 Review of E1's Current Approach

Table 369 below outlines for each program component, the NTGR results, what measures or sub-categories are included in the NTGR, the current type of spillover measured and the last date the NTGR approach was updated. The results included in Table 369 reflect those used in the 2023 Evaluation. Programs marked with an "\*" indicate program components for which the NTGR will be re-evaluated as part of the 2024 Evaluation. The "Proposed changes?" column provides a recommendation for any changes to be considered given the principles above on spillover and the inclusion of measures. Deemed NTGR ratios of 1 are used for programs targeted at low-income participants (MHEEP, ASFH, AMH) as well as SEM.

**Table 369: Summary of E1's Current NTGR Approach**

| Program Component | Measures for Which FR Is Established                                                                                                                            | Year of Last FR Update | Current Spillover Methodology                                                                                                                         | Year of Last Spillover Update | Proposed Changes                                                                                                                                          |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| ARet              | FR determined for all measures except dehumidifiers, FR deemed as nil for dehumidifiers, <sup>408</sup> FR established at 43% for fridges and 45% for freezers. | 2022                   | Like spillover established at 0%.                                                                                                                     | 2018                          | N/A                                                                                                                                                       |
| IS*               | FR determined for LED bulbs (59%) and fixtures (49%). For other measures, FR deemed as nil.                                                                     | 2023                   | Like spillover is captured by measuring market effects <sup>409</sup> at the retailer level, established at 9% for LED lamps and 2% for LED fixtures. | 2023                          | Review and update NTGR approach given product mix is expected to change significantly in 2025, including a review of assumptions for any deemed measures. |
| HEA*              | FR determined for all measures. NTGR established overall and by category – solar PV (26%) and energy efficiency upgrades (17%).                                 | 2023                   | Like spillover established at 1%. Partial participant spillover (for those who complete D but not E assessment) established using a deemed value.     | 2023                          | Include unlike SO since there is an education component in HEA.                                                                                           |
| GH                | FR determined for all measures. NTGR established overall and by category – biomass (47%), MSHPs (48%), and DR measures (9%).                                    | 2023                   | None as opportunity for spillover deemed limited.                                                                                                     | N/A                           | Consider collecting information on like spillover for completeness (e.g. installing MSHPs in second homes).                                               |

<sup>408</sup> The participation levels for the retirement of other appliance types were too low to reliably assess free-ridership using the survey; thus, for air conditioners and small appliances, the free-ridership levels from the 2018 evaluation were used, while no free-ridership and secondary market impacts were applied for dehumidifiers since none was measured in past surveys.

<sup>409</sup> Market effects capture sales of eligible products that may have occurred due to the influence of Instant Savings even if no discount was offered, for example from retailer staff having better knowledge and awareness of energy efficient products or changes in retailer offerings.

| Program Component | Measures for Which FR Is Established                                                                                                                                    | Year of Last FR Update                                                                                                                   | Current Spillover Methodology                                                                                  | Year of Last Spillover Update | Proposed Changes                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|-------------------------------|----------------------------------------------------------------------------------------------------|
| EPI*              | FR established at 25% for LED, 10% for low-flow showerheads. For all other measures, FR deemed as nil. Low-income participants deemed NTGR=1.                           | 2021                                                                                                                                     | Like and unlike spillover (asked about all energy efficiency measures implemented) established at 10%.         | 2021                          | Update to ensure highest savings measures are measured and review assumptions for deemed measures. |
| MHEEP             | Deemed NTGR = 1                                                                                                                                                         |                                                                                                                                          |                                                                                                                |                               |                                                                                                    |

| SBES              | FR determined at 20% for DIY and 12% for Audit path. NTGR established by path - audit, DIY.                                                                             | <ul style="list-style-type: none"> <li>› 2023 - DIY</li> <li>› 2019 - Audit</li> </ul>                                                   | Like participant spillover and partial participant spillover (from dropped-out participants) determined at 0%. | 2023                          |                                                                                                    |

\* NTGR to be updated as part of 2024 evaluation. Note for HEA, only partial participant spillover will be updated in 2024.

## 8.2 Summary of Recommendations

Based on Econoler's review of NTGR best practices using the self-report approach, Econoler has identified several aspects of the current approach that should be maintained and other areas that should be consistently updated across the portfolio moving forward. The free-ridership and spillover questionnaires and algorithms for E1 evaluated DSM programs will be updated where necessary based on the elements below.

## Aspects Maintained

- › The overall adjustment approach to **cross-influence** currently used in E1 algorithms. This approach captures influences outside the program (e.g. past participation, educational initiatives, etc.), the results of which are then applied to total free-ridership score results.
- › The current method of capturing **spillover** with a focus on like spillover. Unlike spillover should be considered when a program is designed to influence participants to take further actions beyond what is included in the program (e.g. the educational aspect of EPI).
- › **Consistency checks.** Questions that serve to check for contradictions, compare responses to similar questions, and remove inconsistencies from the NTGR calculation continue to be important. Open-ended questions can be included for programs involving larger projects to provide context and a further consistency check.
- › **Number of questions.** The current questionnaire design (number of questions and framing) can be maintained, although language efficiencies may be employed where appropriate (see Key Changes below).

## Key Changes

- › **Averaging the intention and influence scores** to calculate free-ridership. This updated approach adopted by several jurisdictions ensures that both variables carry an equal weighting as decision-making factors. Econoler recommends that E1 move away from their current approach which weighs intention score higher than influence to this new approach.
- › Using a **four-point unbalanced scale** for free-ridership and spillover. Answer scales in E1 algorithms primarily use a 10-point numbered scale approach whereby only the first and last points of the scale are labelled. Econoler recommends moving to a four-point ordinal scale whereby all points are distinctly labelled for improved survey participant comprehension. The proposed scale is unbalanced since each scale point must be scored incrementally for the free-ridership algorithm.
- › **Simplifying question wording where possible.** Simple questions where possible help ensure clarity and comprehension for survey respondents. Econoler will continue to pre-test questionnaire changes among small respondent samples to ensure that questions are correctly understood before fully launching any survey.
- › Ensuring that the NTGR is considered for all measures, either utilizing a **deemed ratio or program-level ratio when not measured.** This would be the case for multi-measure programs (e.g. EPI) where it is not possible to collect data on all measures.

## 9 Program Algorithms

In the subsections that follow, two E1 program algorithms are evaluated in more detail – those of EPI and BER-IR as examples as the NTGR for these programs will be updated as part of the 2024 Evaluation. For each algorithm, the Evaluator reviews the elements listed below to ensure they are aligned with best practices and the guidelines above and, if not, makes adjustments.

- › Algorithm variables included
- › Question design
- › Question wording
- › Response categories and scales
- › Scoring mechanism
- › Consistency checks

The tables for each algorithm are organized into two main sections: One for the questions, answers, scoring mechanisms, and consistency checks currently used in the algorithm (columns under the “Current Algorithm” heading); and one for the questions, answers, scoring mechanisms, and consistency checks recommended for the revised algorithm (columns under the “Adjusted Algorithm” heading). Any revisions made are presented using a light green background.

## 9.1.1 Efficient Product Install Algorithm

Below is an example of the free-ridership algorithm for the measure that generates the highest savings in EPI: LED lamps. Please see Section 9.1.3 for an example calculation. Econoler will adapt the free-ridership algorithms for the other EPI measures generating significant proportions of savings for the program (smart thermostats and domestic hot water measures). For the measures that constitute low proportions of the savings, Econoler will use a deemed NTGR based on historic values or research in other jurisdictions (or both).

**Table 370: Free-Ridership – LEDs**

| Current Algorithm |                                                                                                                                                                                                                                                      |                            |                     | Adjusted Algorithm                                                                                                                                                                                                  |                                                                                                                                          |                     |

| B3                | [ASK IF B1=1-6 OR 96 OR B2=2] I'd like to learn more about what influenced your organization's decisions to use these strategies to sell <EFFICIENT PRODUCT> this year. For each of the six following items, answer using a 0-10 scale, where 0 means that the item did not influence at all your organization's decisions to use these sales strategies, and 10 means that the item had a great deal of influence on your use of the sales strategies. To what extent did you use these sales strategies because of?<br>a. The incentives offered by ENS<br>b. The educational, promotional and marketing efforts and support provided or driven by ENS<br>c. The quality or great value of <EFFICIENT PRODUCT><br>d. Your organization's policies and desire to support sustainability<br>e. Your organization's interest in increasing your sales and profits | 1) Answer: __ (scale 0-10) | MAX(B3a; B3b)      | [ASK IF B1=1-6 OR 96 OR B2=2] Please indicate the influence of the following six factors on your company's decision to use the strategies we just talked about to increase your sales of <EFFICIENT PRODUCT> this year. Was [INSERT FACTOR] very, somewhat, not very, or not at all influential on your company's choice of these sales strategies?<br>a. The incentives offered by ENS<br>b. The educational, promotional and marketing efforts and support provided or driven by ENS<br>c. The quality or value of <EFFICIENT PRODUCT><br>d. Your company/organization's policies and desire to support sustainability<br>e. Your company/organization's interest in increasing your sales and profits | 1) Very influential (100%)<br>2) Somewhat influential (75%)<br>3) Not very influential (25%)<br>4) Not at all influential (0%)<br><br>MAX (B3a; B3b) (%) |

| B4                    | [ASK IF B1=1-6 OR 96 OR B2=2] The factors we just discussed can be divided into two categories: those that relate to the BER program (the incentive, the educational, promotional and marketing efforts and support provided or driven by ENS), and those that are external to the program (the product quality, your organization's sustainability policies or your organization's desire for increased sales).<br><br>I'd like to know the influence of each of those categories on your organization's decision to use the sales strategies we discussed earlier. In percentage points, out of 100% in total, what would be the influence of the program-related factors versus the influence of the non-program-related factors on your organization's decision to use these sales strategies? In other words, what is more or less likely to explain why you use these strategies? [MAKE SURE THAT B4a+B4b=100%] | a) Points awarded to program factors: _____%      | B4a = Answer (%) | [ASK IF B1=1-6 OR 96 OR B2=2]<br>The factors we just discussed can be divided into two categories: those that relate to the BER program (the incentive, the educational, promotional and marketing efforts and support provided or driven by ENS), and those that are external to the program (the product quality, your organization's sustainability policies or your organization's desire for increased sales).<br><br>I'd like to know the influence of each of those categories on your organization's decision to use the sales strategies we discussed earlier. In percentage points, out of 100% in total, what would be the influence of the program-related factors versus the influence of the non-program-related factors on your organization's decision to use these sales strategies? In other words, what is more or less likely to explain why you used these strategies? [MAKE SURE THAT B4a+B4b=100%] | a) Points awarded to program factors: _____%      | B4a = Answer (%) |

### 9.1.3 Calculation Example

Below is a calculation example of the adjusted free-ridership algorithm for LED lamps in EPI for one participant's responses (responses indicated by green highlight).

**Table 375: Free-Ridership – LEDs**

| Adjusted Algorithm |                                                                                                                                                                                                                     |                                                                                                                                                                                                      |            |     |
